The position in which the rouge should be applied depends upon the basic shape of the face, and the following table gives an indication of the method that should be adopted in applying rouge to faces of various shapes.

#### APPLICATION OF ROUGE.

Shape of Face.	Placing of Rouge.
Round	High on the cheek-bones, near the nose, and just under the eyes. This makes the face look longer and less broad or round. Avoid the outer edges of the cheeks.
Oval	Within the triangles high at the sides of the cheeks, from just below the temples down to a point level with the nose tip, and then outwards and upwards towards the ears.
Long	Low down on the cheeks, spread over a wider area than normal.
Broad	In a comparatively long and thin line down the sides of the cheeks.

**Application of Lipstick.** Like rouge, lipstick when properly applied can alter the characteristics of the face and improve the general appearance. Narrow lips can be made wider and fuller, while broad lips can be narrowed and made to look more attractive. As a general rule, the best plan when applying lipstick is to outline the natural arches of the lips to form an attractive "Cupid's bow" and to blot the excess of lipstick with a paper tissue. If the mouth is wide, the lipstick should not extend right to the corners, whereas if it is narrow, the corners of the mouth can be accentuated by continuing the lipstick to the fullest width of the mouth.

The shade of lipstick to employ varies a good deal with fashion, but it should always be chosen to harmonise with the natural colours of the hair and complexion and with the general colour scheme of the clothing (see table p. 821).

**Artificial Light and Make-up.** Many cosmetics, especially face powders and lipsticks, alter in appearance when seen in artificial light. In general, for evening wear a brighter or pinker shade of powder should be used than that which is applied during the day-time. If, in the case of fresh-complexioned people, a pinkish powder is employed for day-time use, the corresponding shade for evening wear is a slightly more bluish or

mauve shade. Women with sallow complexions in particular, should pay more attention to the shade of their face powder in artificial light and avoid the purely yellow shades of powder, e.g., Rachel and Ochre, otherwise the effect of yellow artificial light merely increases the sallow appearance of the skin.

Much the same considerations apply to the choice of lipstick for night use. Because of the yellowness of artificial light, lipsticks containing a little blue or mauve can be used, even by those people who would not be suited by them in the day-time.

Eye cosmetics are also influenced by the type of lighting (see eye shadow and mascara charts below).

**Toilet Equipment.** It is important to keep the various equipment used for cleansing and adorning the face scrupulously clean, by frequent washing whenever possible. This applies particularly to hair-brushes, face-flannels, and nail-brushes. Powder-puffs should be kept covered and also washed occasionally, while cotton-wool should not be used more than once, and should be burnt or thrown away after use. The following list of toilet accessories will cover most needs:

1. A wash-cloth, fairly rough in texture and conveniently made from terry towelling or similar fabric.
2. A hair-brush with long bristles but of medium hardness. Very soft or very hard brushes should be avoided.
3. A comb with smooth, rounded teeth, preferably not made of metal, since this tends to damage the hair.
4. A stiff nail-brush. The modern ones with nylon bristles will be found very efficient and have a long life.
5. Cotton-wool or paper tissues.
6. A powder-puff of adequate size, preferably washable.
7. A tooth-brush of medium hardness.
8. Eyebrow tweezers.
9. A nail file. This often forms part of a complete set of manicure tools conveniently boxed. Other essential aids to manicure are orange sticks, an emery board, and nail clippers.
10. Hair-net for protecting the hair after setting.
11. Setting pins.

#### EYE COSMETICS.

**Eyebrows.** The shape and character of the eyebrows can have a big influence on facial expression. Eyebrows which are almost invisible, either because of the sparseness of the hairs or because they are very fair in colour, can be accentuated with a brown or black eyebrow pencil. Before the pencil is applied, the eyebrow should be carefully trimmed with tweezers if necessary. When doing this, remove only the hairs which are outside the natural line of the brow and those which are on the bridge of the nose. The plucking of eyebrows can be made less painful by first bathing them with warm soap and water and after drying softening them with a little greasy cream. If the hair of the eyebrow is thick and bushy and would benefit by thinning, the hairs should be plucked only from the underside. By doing this, the eye itself is made to look larger and more attractive. Eyebrow pencils, or indeed, any kind of eye cosmetic, should never be applied under the lower lashes. Either a brown or a black eyebrow pencil will suit most needs. The brown pencil should be used by those with medium or blonde hair and the black for those with dark brunette hair. Sometimes a reddish-brown eyebrow pencil can be used effectively by red-heads.

**Eye Shadow.** The purpose of eye shadow is to make the eye appear deeper and brighter or more luminous. It is not advisable to use eye shadow at all during the day-time, but for evening wear a

#### EYE SHADOW CHART.

Eyes.	Pale Blue.	Deep Blue.	Grey.	Hazel or Green.	Brown.
Day	Pastel Blue	Deep Violet	Pastel Blue	Grey Green	
Night	Light Mauve or Silver Blue	Deep Blue	Silver Blue	Green or Silver Green	Green

sparing application to the outside of the upper eyelid can give a pleasing effect. Eye shadow should never be used on the lower eyelid. Eye shadows are made in a very wide range of shades, and are in the form of creams, which should be applied very lightly with the finger-tip. A little should be put on to the centre of the eyelid and smoothed outwards to give an even appearance. The chart on p. 820 gives an indication of the shades which are best suited to the various eye colours. Eye-shadow shades for day-time use have been included, but except for special occasions, it is not generally advisable to use eye shadow in the day-time. Often a little oil or brillianine smeared over the top lid provides a more natural touch for day use, but if eye shadow is used, great care should be taken to apply it extremely lightly.

**Mascara.** The use of mascara enables the darkness and the apparent length of the eyelashes to be increased. By using it intelligently, the brightness and expressiveness of the eyes can be improved. It needs a little practice in order to apply mascara successfully and to avoid getting the mascara on to the eyes or on to the upper lids. Mascara is best applied to the upper lashes only, because if the lower lid is treated, it gives the appearance of a shadow under the eyes. Mascara is normally made in the form of a small block which is moistened and the colour applied to the eyelashes by means of a specially made brush. In applying it, it should be put on lightly in the centre of the eyes and more heavily at the outer corners. This creates an illusion of the eyes being set wide apart. After the mascara has been put on with the brush, any excess which can be seen clinging to the lashes or which has strayed on to the eyelids, should be removed by means of a little pad of cotton-wool wrapped round the end of an orange stick.

The main shades of mascara are black and blue. The black should be used on dark-brown or black eyelashes, and the blue by women with blue or grey eyes. The effect in this case is to accentuate the apparent blueness of the eyes. Green mascara is occasionally used by red-heads and blondes, but it produces a very striking and exotic effect, and is not to be recommended for everyday use.

**Glasses—Styles to Suit Faces.** Those who are obliged to wear glasses should pay some attention to the shape of the frames, because they can influence one's attractiveness for good or bad. Thus the upper curve of the frames can follow the arch of the eyebrows or the curve of a high cheekbone. People with round, broad faces will benefit by choosing glasses with wide frames, narrow in depth, like the shape of a cat's eye. Such frames can do a great deal to lessen the apparent width of the face. Now that it is possible to obtain glasses without the lower rim, more of the natural beauty of the eye can be seen, and indeed, these have much to recommend them, as compared with the conventional heavy tortoiseshell, which too often give the face an owl-like look, especially if they are of a dark colour.

Spectacles which are so made that they sit well up on the nose can make a short nose look longer, and vice versa.

There is a wide choice of colour in spectacle frames, but, in general, it is best to avoid very striking shades. The idea should be to make the spectacles inconspicuous in themselves but allow them to contribute to the general smartness of one's appearance. One of the safest and smartest materials to choose is a light-coloured tortoiseshell, which looks elegant on most faces, while for those who wish to experiment a little with colour, blue frames can bring out the colour of the eyes, while green frames, like many other accessories of this colour, seem to suit red-heads.

**Lip Cosmetics.** Adornment of the lips is usually achieved by the use of lipsticks in various shades (see "Application of Cosmetics"). There are also available, however, lip salves, which are either white or lightly coloured, and whose primary function is not so much to beautify the lips as to keep them in good condition. They are of especial

value in cases of cracked or chapped lips, and can be used with advantage to protect the skin of the lips in severe weather.

In recent years preparations have been made for the lips which are of the nature of lacquers, and they are sometimes referred to as "lip rouges." They really consist of varnishes, suitably coloured with different dyestuffs, and they leave a film over the lips which is waterproof, and yet which lacks the soft greasiness of lipstick, and so does not mark off on to crockery, cigarettes, etc. These lacquers are the nearest approach yet achieved to a kiss-proof lipstick, but their regular use is not to be recommended, because they so easily cause dryness and even cracking of the lips.

## THE HAIR.

**Brushing and Combing.** Hair which is to look attractive must be kept clean and in good health. This means that the natural supply of oil to the hair must be maintained, and one of the simplest methods of stimulating the flow of natural grease is by scalp massage. This is not necessary in the case of naturally greasy hair, but dry scalps benefit considerably by a daily massage treatment, coupled with the application of a suitable lotion.

Apart from this, the hair should in any case be combed and brushed at least once daily, preferably before going to bed, because this helps to distribute the natural grease evenly throughout the hair, as well as to remove the dust which has accumulated on it during the day. It is best to use a brush with relatively stiff bristles so as to stimulate and cleanse the scalp as well as the hair, but the brush should not be so hard that it becomes slightly painful to use it. In this case there is a risk that some of the hair, especially if it is fine in texture, may be broken or even pulled out by the roots. For similar reasons, the comb should have teeth with rounded ends, and a useful type is one which consists half of widely spaced teeth and half of finely spaced teeth. The hair should first be combed through with the wide comb in order to remove tangles without too much pulling, and then the fine end of the comb should be passed through the hair to straighten it out and to remove the clinging dust more effectively.

Brushing should always be in the direction of the hair growth from the crown outwards, and it should be continued for two or three minutes each day.

Massage of the scalp with the finger-tips assists the secretion of the natural oil, as well as loosening dandruff, and it is best to give the massage treatment before a final brushing and combing. The finger-tips should be placed firmly on the scalp, which is then rubbed over its whole area until the skin can be felt to move over the underlying skull. Tonic lotions and spirit hairdressing preparations can very suitably be applied in conjunction with scalp massage.

**Shampoos.** Regular washing of the hair is essential to keep it in good health and condition (see "The Hair and Scalp"). There are very many excellent shampoos on the market, and these are to be preferred to washing with ordinary toilet soap, because they are specially made for the purpose.

Soap shampoos in powder or cream form give excellent results, especially in soft-water districts, and they have the great advantage of leaving the hair nice and soft, but easy to set. If soap shampoos are used in hard-water districts, it is an advantage to follow the shampoo with a mild acid rinse to free the hair from any hard-water deposits. Many soap shampoos are provided with a suitable rinsing powder, but if this is not used, the hair should be rinsed through with water to which a little lemon juice or vinegar has been added.

Generally, however, in hard water soapless shampoos will be found more satisfactory, and these can be obtained in powder, liquid, or cream form. The various types all give excellent results, and the choice between them is a matter of personal preference and convenience.

The best method to follow in shampooing the hair is first thoroughly to wet it and then to add the shampoo a little at a time, rubbing it well into

the scalp with the finger-tips. Soap shampoos are usually used with a single application, whereas soapless shampoos are best divided into two portions, applied separately with a rinse in between. The shampoo should be worked well into the hair, until a good lather is obtained, and then rinsed off. The best and most convenient method of rinsing is by means of a spray, but if this is not available, a wide-mouthed jug or even a tumbler can be used. Rinsing should be thorough, and no trace of lather should be left on the hair. During both the shampooing and the rinsing, the hair should be rubbed from the crown of the head outwards, as by this means it becomes less tangled and is easier to comb later.

Special types of shampoo are made containing mild colouring agents, such as camomile and henna, and these should be used by blondes and brunettes respectively, following the maker's instructions. Their main value is not actually to colour the hair, but to add a little brightness to its appearance.

**Oil Shampoo.** This is a special type of shampoo, and as its name implies, it is oily in appearance and yet can be easily rinsed away with water. Oil shampoos are particularly suitable for people with dry and brittle hair, and in contrast to the normal type of shampoo, they do not produce a lot of lather. The oil shampoos are applied directly to the dry hair and massaged well into the scalp and along the length of the hair so that the whole head becomes saturated. They are then rinsed off and the hair combed and set as usual.

**Conditioning Treatments for the Hair.** Although oil shampoos provide a form of conditioning treatment, special preparations in liquid or cream form are available for improving the feel and texture of dry and brittle hair. Hair sometimes loses much of its "nature" through overbleaching, exposure to the sun, or as a result of permanent waving. In such cases a conditioning treatment can be of considerable benefit. The conditioning cream or lotion can be given as a separate treatment rubbed into the hair and scalp, or it can be applied immediately after a shampoo while the hair is still wet. The effectiveness of the conditioning treatment can be improved by wrapping the head in a hot towel after the cream or lotion has been applied and leaving it for 2 or 3 minutes before rinsing off. Hair which is excessively greasy benefits from an after shampoo friction treatment with Eau de Cologne or Toilet Water. This can be sprinkled on to the wet hair after shampooing, massaged well into the scalp, and then dried off with a towel, followed with a good combing and brushing.

**Dry Shampoos.** Dry shampoos for women's use are absorbent powders which are intended for those people who find it inconvenient or undesirable to wash the hair with water. The powder is distributed evenly throughout the hair and on the scalp, so that it has a chance to absorb all the grease and dust, and is then removed by vigorous brushing.

Dry shampoos for men consist of soap dissolved in spirit, the liquid being applied to the dry hair and rubbed in until a lather is worked up. The surplus lather is removed with a damp sponge and the hair towelled dry. Both types of dry shampoo are intended to provide a quick means of cleansing the hair, though neither is as thorough in its cleansing action as that of a normal soap or soapless shampoo.

**Drying and Setting.** After shampooing or any other hair treatment which involves wetting the hair, the larger part of the water is removed by rubbing with an absorbent towel, preferably a warm one, and the hair should then be well combed to make sure that it is free from knots and tangles. To set the hair into a desired style is not easy, unless a comparatively simple style is desired, and in any case the use of a setting lotion will be found of considerable help. These can be applied by sprinkling on to the hair, or better, by dipping the comb into the lotion and then passing it through the hair several times. The application of a setting lotion speeds up the drying time of the

hair, makes it more easy to set into waves and curls, and confers more permanency on the waves when the hair has dried.

Successful setting of the hair without assistance can only be achieved with practice, although modern short hair styles make setting much easier than it was at one time.

It is, of course, best to set the hair at night so that the set style can be kept in place by wearing a hair-net during sleep. A good idea is to set the hair before having a bath—the steam which usually fills the bathroom helps to set the hair.

Hairdressing styles are subject to changes in fashion, and it is best to find from experience which particular style best suits the shape of the face and one's height and colour.

**Permanent Waving.** Curly or wavy hair is generally considered to be more attractive than straight hair, and from the earliest times women have sought to impart a wavy appearance to their otherwise naturally straight hair. It is known, for example, that in ancient Egypt women used wet mud for curling their hair.

It is only during the past 50 years that waving of hair has been systematically studied. Prior to that, hot irons or tongs were used, but to-day there are available a number of different methods of producing attractive waves in straight hair.

Professional permanent waving demands a considerable degree of skill, as well as the necessary suitable equipment. The basic principle of the permanent wave is that the hair is softened by means of a special chemical reagent, and then heat is applied to it while it is wound on curlers. This process causes chemical changes to take place in the structure of the hair so that it remains in a permanently curled state after the treatment. Any new growth of hair after waving is, of course, in the original straight condition, and the wave is therefore only relatively permanent and lasts an average time of about six months. At the end of this period the hair has grown to such a length that only the ends retain the original wave. The choice of any particular system of permanent waving must depend upon individual preference and on the style of wave which it is desired to produce. By varying the method of application of the waving treatment and its time, the hairdresser can produce tight or soft curls, and can adjust the treatment to suit individual heads of hair.

In recent years what is known as "cold waving" has been very considerably developed. As the name implies, no heat is necessary, and the hair is first wound on curlers in the usual way and then moistened with a special chemical reagent which softens the hair while it is in the curled state. After sufficient time has elapsed for adequate softening, the hair is hardened again by the application of a second lotion referred to as the "neutraliser," and it then remains fixed in a wavy or curled form. Some modern cold waves for home use, however, do not require any neutraliser. In general, cold waving produces a slightly softer wave than the majority of the hot methods, and it is, of course, more comfortable to the client, and does not require the use of comparatively expensive and elaborate equipment for heating the curled hair.

Other systems of so-called "tepid" waving have been devised, and these employ a combination of the hot-waving technique and that of the cold wave.

**Home Permanent Waving.** With the discovery of the cold waving process for hair, it has become possible to provide waving preparations for self-application at home. These work on exactly the same principle as the professional cold wave, but some skill is required on the part of the user in dividing the hair into appropriate sections and winding them on curlers for treatment with the lotion. In all cases the manufacturer's recommendations should be carefully followed, and home perms should be applied very cautiously to hair that has been bleached or dyed. Bleached hair reacts very vigorously to cold-waving lotions, and over-treatment can result in damage; while in some cases dyed hair may change colour as a result of permanent waving. In such cases, the manufacturers of home perms give special instructions.

With practice, the home permanent wave can

produce very satisfactory results, but it is usually much easier if the assistance of a second person is obtained to manipulate the hair during the process.

**Hair Dyeing, Tinting, and Bleaching.** Bleaching the hair consists, of course, in removing some or most of its natural colour by chemical treatment. Care should be exercised in the application of bleaching preparations, and on no account should they be used other than according to the maker's instructions, or if simple peroxide of hydrogen is employed it should be applied in a diluted form and the treatment given very gradually over a period. If the bleaching is done quickly with strong concentrated lotions, the hair loses a good deal of its strength, and is apt to split and even break off when it is combed.

It is generally preferable and safer to use a proprietary bleaching preparation and to follow the instructions provided.

Dark or mousy hair can often be improved in appearance by the application of brightening preparations, of which the commonest are based on camomile for blonde hair and henna for dark hair. These are often in the nature of shampoos containing small amounts of colouring matter, which is deposited on the hair and produces a superficial lightening of colour. They are available in both powder and liquid form, and are quite suitable for home use. Hair dyeing is best undertaken by a professional hairdresser, because it is extremely difficult, if not impossible, to apply dyes to one's own hair and obtain an even and pleasing result. The hair must first be thoroughly cleansed, and it is usual to give a preliminary mild bleaching treatment, especially if the desired shade is lighter than the natural colour of the hair. The dye must also be applied with due attention to the gradations of shade which are always present in naturally coloured hair. Furthermore, a few people are sensitive to some widely used types of hair dye, and it is necessary to make a preliminary test on the skin in order to avoid trouble when the dye is finally applied.

Of the hair dyes available, natural henna, which produces a coppery red shade, and various modifications of henna to produce other shades have been used for a very long time. They have the advantage of being completely safe and of not affecting the skin, but they do not produce such naturally pleasing shades as the more modern dyes.

Perhaps the main value of hair dyeing is in retouching grey or white hair, but it is, of course, necessary to re-apply the dye at regular intervals to the new growth of hair, because this appears in its natural colour.

**Brilliantines and Other Hair Dressings.** Brilliantines, which now consist of light mineral oil suitably perfumed and sometimes coloured, are used by both men and women for keeping the hair in place and for imparting a gloss to the hair. They are of special value to people with naturally dry hair, because this type of hair, being deficient in natural oil, tends to appear dull and to feel harsh.

For women, brilliantine should be applied sparingly, and it is often useful to rub a little brilliantine over the surface of the hair while it is still wet after shampooing and to comb it through the hair, so that after drying an increased gloss is obtained. Alternatively, the brilliantine can be sprayed lightly over the surface of the hair, which should then be combed or brushed to distribute the brilliantine evenly over the surface.

Some brilliantines are known as "separable," and they consist partly of oil and partly of spirit lotion. They must be well shaken before being applied, and they are less greasy than the non-spirit brilliantines, which consist entirely of oil without spirit.

Brilliantines of both types are suitable for men with fine or sparse hair, but those with heads of thick, coarse hair usually require a preparation with greater fixative qualities than brilliantine to keep the hair in position.

Hair-fixative preparations can be either oily or non-oily, the latter being more suitable for people with naturally greasy hair. They contain special fixative materials which when allowed to dry on the hair stiffen it slightly and keep it in a fixed

position. They are usually in cream form, and only sufficient should be applied to the hair to keep it in position. Other preparations available for applying to the hair are lotions which can contain various tonics or medicaments designed to cleanse the scalp and to be combined with a massage treatment. One of the earliest of these lotions was bay rum. They usually contain a considerable amount of spirit, and when applied they should be well rubbed into the scalp with the finger-tips. They are of considerable assistance in freeing the scalp from dandruff and keeping it clean and healthy. People with naturally greasy hair should use a plain spirit lotion, whereas those with dry hair should use a preparation that contains a proportion of oil.

In recent years dressings for the hair have been made in the form of lacquers, which are usually sprayed on to the hair and which are intended for use on special occasions. Their effect is to fix the hair in its special style, and they are therefore of most value when a rather elaborate or exotic style has been chosen for a special occasion. The lacquers can be either plain, or special effects can be produced by coloured lacquers, including gold, silver, and copper.

Special effects can also be produced by treating selected parts of the hair with lacquers or with metallic powders and liquid creams. The application of these, however, is best left to a professional hairdresser.

**Hair Styles.** Hair styles are very much subject to fashion, and it is not, therefore, possible to give more than a little general guidance on this subject. It is best to consult a professional hairdresser as to the style of hair which will suit one's face and be in line with the current fashion of the day. The style in which hair is dressed can help to alter the apparent shape of the face and to make less noticeable facial peculiarities. For example, a round face can be made to look longer by a style of hairdressing in which the top hair is built high above the forehead, and the sides combed away from the face and dressed close to the head. For a long face, on the other hand, the side hair should be curled or built out from the face to give increased width and the top hair dressed fairly flat. Women who have a naturally oval face, can generally wear a much wider variety of hair styles than others, and almost any style can look attractive with this type of face.

**Face and Skin Massage.** The skin of the face and also that of the neck and shoulders can be kept smooth and supple by gentle massage treatment carried out regularly. The massage is applied with the fingers or knuckles using a greasy cream, such as a cold or cleansing, to ease the passage of the fingers over the skin.

Regular massage of the face can help to delay the development of wrinkles and keep the complexion clear. Once a week is the ideal, but even an occasional massage will be found refreshing and stimulating. The routine to be followed is indicated by the series of diagrams below. Smear the cream generously over the whole of the face and neck then:

1. Start with the neck and throat—places that are often neglected, yet it is here that looseness and wrinkling of the skin can be so obvious, giving a "scraggy" appearance. Massage the cream into the neck with the backs of both hands, using firm, upward strokes—from the base of the throat to the chin. Finish by flipping the hands under the point of the chin in a vigorous slapping movement.

2. Massage outwards from the point of the chin along the lines of the jaw-bones, using the finger-tips in a firm, circular movement. Make sure you have enough cream to allow the fingers to slide easily over the surface of the skin without dragging.

3. Continue with the same full circular movements up each side of the face to the temples. Cover the whole of the face from the corners of the mouth, up under the cheekbones and outwards to the ears, but avoiding the skin under the eyes and at the sides of the nose.

4. Now use a gentle patting with the finger-tips to work the cream well into the skin under the eyes, moving downwards and inwards to the nose. Do not massage the eyelids, but a gentle circular massage at the corners of the eyes is beneficial in helping to smooth away wrinkles.

5. Finish the treatment by massaging upwards and slightly outwards from the point of the chin to the lower lip, using a circular movement with the finger-tips. In the same way, work upwards from the bridge of the nose and outwards across the forehead to the temples.

At the same time as the face massage is applied the hands can also be given a simple yet useful massage treatment. Apply plenty of cream and then let each hand massage the other by drawing them over each other from finger-tips to wrists, rubbing the surfaces of the fingers and the spaces in between. Give a special circular massage to the

knuckles and joints, flexing them continuously while doing so.

For massaging the throat, the backs of the fingers or the knuckles should be used. The movements should start low down on the throat and continue upwards, with firm pressure, to the chin and jaw-bone. Following this, the sides of the jaw and the chin should be slapped vigorously in order to preserve the contour.

For the base of the neck and to avoid the development of folds and wrinkles giving a scraggy appearance, massage with the knuckles away from the neck and along the line of the shoulders.

Massage treatment on both face and neck should be followed by the removal of the surplus cream with a pad of cotton-wool, or a tissue, leaving enough of the cream on the skin to soak through during the night. If the skin is naturally greasy, however, it is better to follow the massage by treatment with an astringent lotion or milk.

**Sun-bathing Preparations.** Sun-bathing should be indulged in with moderation, when it can be a valuable tonic. It is unwise to expose one's skin to blazing sunshine for more than short periods, because excessive exposure will produce headaches and very often burns and blisters which spoil the texture of the skin. The most vulnerable spots, which are likely to be attacked first by bright sunshine, are the nape of the neck, the shoulders, the knees, the hands, the backs of the legs and heels, and the V of the neck which is usually exposed when wearing a summer frock.

Even when the skin has become accustomed to exposure to sunshine, it is always better to apply some protection to it before sun-bathing. Specially prepared oils and creams are available, some of which contain brown colouring which stains the skin and enables the sun-bather more rapidly to acquire the desired tanned appearance. Sun-bathing oils and creams will not protect the skin completely, but their use will enable tanning to take place gradually and pleasantly, without excessive redness and blistering. They act by filtering out some of the heat rays in natural sunshine, and they allow the development of protective pigment in the skin to take place gradually and evenly. Special care should be taken to protect the neck and shoulders before sea-bathing. Because the body feels cool in the water, it is often forgotten that the sun's rays are still exercising their burning action. The area of skin not covered by the bathing costume, should be treated with cream or oil before sea-bathing.

In summer-time, whether the skin is deeply tanned or not, deeper shades of face powder can be used than in the winter months. A good plan is to provide oneself at the beginning of the summer with two boxes of powder, one with the shade normally used and the other of a darker suntan colour. As the summer proceeds and the skin becomes tanned, more and more suntan powder can be mixed with the normal shade.

**Superfluous Hair.** In the summer-time especially it is desirable to rid oneself of superfluous hair under the arms and on the legs. Various methods are available for removing unwanted hair, the cheapest and easiest of which is shaving with a razor. Other methods which are effective are to apply a special type of wax which is brushed on the area to be treated while warm, allowed to cool, and then pulled off, bringing the hair with it. This, however, is a method which requires some skill, and is probably better carried out by a trained beauty specialist.

Special depilatory creams are available which soften the hair to such an extent that it comes away from the skin, but care should be exercised in the use of these preparations, and they should be applied only at intervals of about a week. Superfluous hair on the legs, unless it is very coarse and strong, can be removed and kept in check easily and painlessly by the use of a special abrasive block, cloth, or glove, which remove the hair by rubbing it off. After the use of a depilatory or any other treatment for removing superfluous hair the cleansed skin should be treated with a little cold or cleansing cream to soothe and protect it.

#### THE TEETH AND DENTAL PREPARATIONS.

Regular brushing of the teeth and gums and cleansing of the mouth are the surest safeguards

against the development of premature decay (see pp. 819-20). In brushing the teeth a systematic technique should be employed which is illustrated in the diagrams below, Figs. 4-7. The choice of tooth-brush is important, and except where the gums are unusually tender, it is best to choose a medium/hard brush with bristles that are stiff enough to remove all the particles of food lodged between the teeth, and yet not too stiff to damage the sensitive surface of the gums.

Many excellent preparations are available to assist the action of the brush, and these all consist of a cleansing agent especially designed for the purpose, together with a polishing ingredient to

FIG. 4.—Clean the inside and the outside surfaces of the back teeth by rolling the bristles over the gums and teeth toward the grinding surfaces.

FIG. 5.—Clean the outside surfaces of the front teeth with the same brushing motion, rolling the bristles firmly into all the grooves and spaces from the gums to the biting surfaces.

FIG. 6.—Clean the inside surfaces of the front teeth, drawing the brush forward from the gum line to the biting edge. Spend the same amount of time on each tooth so that all are cleaned equally.

FIG. 7.—Clean the grinding surfaces (top and bottom teeth) by forcing the bristle well into the grooves and vibrating the brush backwards and sideways. Make sure you have brushed every surface of every tooth.

impart a good lustre and whiteness to the teeth. Dentifrices are sweetened and flavoured in various ways, and since they are all efficient cleansers, a choice between the different types is a matter of personal preference.

Solid dentifrices are made in cake form, and are probably the most economic of the various kinds. Tooth powders, which were very popular at one time, are not so commonly used to-day but they, too, are economical in use, since very little powder need be sprinkled on the brush. The most popular type of dentifrice is the toothpaste packed in a collapsible tube. This has the advantage that there is no waste, and there is a very wide variety of brands available, which differ in flavour and foaming qualities, so that individual tastes can be met. The use of special mouth washes has

much to commend it, and indeed, if it is not always possible to brush the teeth, rinsing the mouth with an antiseptic preparation after meals can assist considerably in freeing the teeth of food debris.

Artificial teeth should be kept scrupulously clean, and should be thoroughly brushed, using a specially designed denture brush at least once a day, and preferably after every meal, though this, of course, is not always possible. Special preparations are available in which the dentures can be soaked in order to keep them perfectly clean and fresh. Ideally the dentures should be left in the mouth during sleep, but for those who remove their dentures at night, an overnight soaking in one of the special denture cleansers is an efficient way of keeping them clean. In any case, they should be given a soaking treatment of about 20 minutes, and this can conveniently be done while some other part of the toilet is being attended to, such as taking a bath or shaving.

It should be a golden rule that the dentist should be consulted at regular intervals, preferably once every six months. Such regular visits enable the development of decay to be discovered in its very early stages, and appropriate treatment can then be given which is both effective and usually painless. Once decay has been allowed to progress and to bite deeply into the tooth, then the treatment is more lengthy, but may still be carried out with local anaesthetics and a minimum of pain. Regular dental inspection is of particular importance in childhood, and all children should be taught to look after their teeth by daily brushing and cleansing. If this is done there is no reason why a complete set of perfect teeth should not be kept during one's lifetime.

### THE HANDS AND NAILS.

**Effect of Soaps and Detergents on the Hands.** The skin of the hands, like that of the rest of the body, is protected and kept in a soft and healthy condition by the natural grease which the skin is constantly secreting (see p. 818). When the hands are immersed for long periods in soap or detergent solutions, most of this grease is removed, and strange as it may seem, the skin also loses some of its natural moisture. The result is that it becomes more sensitive to atmospheric conditions and also to mechanical friction, such as it is subjected to in washing clothes or scrubbing floors. The busy housewife must, therefore, take especial care of her hands if she wishes to keep them in an attractive and good condition.

A number of preparations specially made for the hands are available, and it is advisable to apply one of these whenever the hands have been exposed for long periods to the action of water or washing agents. A simple mixture of glycerine and rose water, or glycerine in the form of jelly can help a good deal in keeping the hands soft and smooth, but the modern creams and lotions are even more effective. By regularly applying a liquid lotion or a cream containing a proportion of oil after the hands have been exposed to water, the natural moisture and grease contents of the skin can be replaced. Skin which is deficient in grease is much more susceptible to chapping by the drying action of wind, because it loses moisture more rapidly than the moisture is replaced by the secretions of the sweat glands.

In recent years protective or barrier creams have been devised which can be applied to the skin before undertaking household tasks which are apt to affect the skin adversely. These barrier creams are of two main types, one of which is water-resistant and should be applied before doing jobs which involve the use of water, and the other is an oil-resistant type which is applied to protect the skin against various kinds of soiling, including oily dirt. The barrier creams should be well rubbed into the skin until they have disappeared, paying particular attention to the nails and the crevices between the fingers. If a barrier cream is not used, a very effective method of protecting the nails is to dig them into a tablet of household soap and fill the space between the tip of the nail and the finger with soap. This prevents the entry of dirt, and when the hands are subsequently washed, the soap comes out carrying any deposited dirt with it.

### MANICURE PREPARATIONS.

**Cuticle Removers.** What is usually termed the "cuticle" of the nail is really the result of the outer dead cells of the skin (which are continually being shed) combining with the natural fatty secretion to form an irregularly shaped appendage around the grooves of the nails. Because of its somewhat unsightly appearance it is usual to remove the cuticle by means of an alkaline preparation generally applied by a little cotton-wool wrapped round the end of an orange stick. More recently cuticle removers have become available in cream form packed in plastic tubes with a pointed nozzle so that the cuticle cream can be easily applied.

**Nail Bleaches and Whiteners.** Bleaching preparations are available for removing various stains such as ink, tobacco, and vegetable juices, from the nails and finger-tips. Such preparations are sold either in liquid or cream form, and they contain a mild bleaching agent. If one of the special nail bleaches is not used, most stains can be removed by treatment with cotton-wool soaked in peroxide of hydrogen.

An even and opaque white border to the nails can be produced by means of nail-whitening preparations, which were originally creams, but which have now largely been replaced by the nail white pencil. The tip of the pencil is simply moistened with water and then applied to the under surface of the nail to give a dense white appearance to the tip.

**Nail Polishes and Lacquers.** A nail polish is an abrasive preparation which increases the gloss on the surface of the nail in the same way that a metal surface can be polished. They are usually powders which are applied by means of a chamois-leather pad specially shaped. Another form of nail polish is a wax pencil which is equally effective in imparting a soft, unobtrusive gloss to the nails.

For a higher degree of gloss, a lacquer or varnish must be used, and these are now available in a very wide range of colours as well as the colourless form. The use of a carefully chosen coloured varnish can effectively contribute to giving the nails and hands an attractive appearance.

In applying nail varnishes the nails should be evenly coated by using the brush provided, and the application should be by even strokes from the base of the nail towards the tip. The extreme edge of the nail should then be wiped free of varnish by means of a tissue or the tip of the finger so as to leave a clear white edge. People who have a tendency towards dry and brittle nails should use varnishes with care, and it may often be advisable not to use this type of preparation at all but to rely on a polishing agent. The drying effect of nail varnishes has been modified a good deal in modern manufacture by incorporating softening oils in the varnishes.

Some of the newer nail varnishes have been made opaque by the incorporation of pigments, and these have the advantage of covering up any minor imperfections in the nail. Similarly the incorporation of gold, silver, or other metallic powders in the varnish enables exotic effects to be obtained, which, however, should normally apply only to evening wear.

As soon as the nail varnish begins to show signs of wear it should be removed and a fresh application made. Special solvents are sold for dissolving nail varnish, and these enable the remains of the old varnish to be removed very quickly and completely.

### CARE OF THE FEET AND LEGS.

It has been said that well over half the adult population suffer some form of foot discomfort, and it is certain that a good deal, if not all of this, could be avoided by giving more personal attention to the care of the feet. Tiredness in the feet affects both physical and mental well-being and often produces bad temper as well as a general feeling of weariness.

The feet have to support the whole of the body, and in addition, because of the conditions of modern civilised living, have to be encased in a sock or stocking and then in a leather shoe or boot. The sole of the foot contains more sweat glands

than any other part of the body except the palms of the hands, and the result is that both socks and shoes very quickly become saturated with perspiration residues left behind by the continuous evaporation of the sweat. It is obvious, therefore, that socks and stockings should be changed and washed frequently so as to prevent the development of undesirable bacteria which may not only cause offensive odours, but may actually lead to skin affections.

**Choice of Footwear.** Provided there is nothing organically wrong with the feet, it is easy to maintain them in a healthy condition by following a simple routine, but it is equally essential that well-designed and well-fitting shoes or boots should be worn. Shoes that are too large can result in the feet gradually becoming malformed, and the whole carriage is affected because an unnatural style of walking is developed. Shoes that are too small, apart from being uncomfortable in themselves, very quickly result in the development of corns and bunions because of the continued pressure and friction of the shoe against the skin. Well-fitting shoes are especially important to people whose work demands a considerable amount of standing, and in such occupations there is sometimes a tendency for the arches of the feet to drop. In such cases arch supports should be fitted by a chiropodist or foot expert (see Medical Section—"Flat Foot").

It is a good investment to buy well-fitting shoes made of good-quality leather. These not only last longer and retain their shape during wear, but they adapt themselves to the movements of the feet during walking and give a greater degree of comfort.

**Foot-baths.** Because the feet are extremities of the body and a comparatively long distance away from the heart, they are particularly sensitive to inefficient circulation of the blood. By themselves the feet get very little exercise, and inadequate circulation is often encouraged by ill-fitting shoes or by tight elastic or suspenders around the leg. Bathing the feet in plain hot water helps to increase the blood circulation and at the same time enlarges the sweat ducts and eliminates stale perspiration residues. If the foot-bath is made alkaline it has an increased softening effect on the outer horny layers of the skin and enables corns and callouses to be more readily removed. Many preparations for foot-baths are designed to provide an alkaline medium, often in conjunction with an oxygen-producing ingredient which assists in cleansing the feet from sweat residues and bacterial infection. Other foot-baths are similar in composition to sea-water and, indeed, paddling or bathing the feet in salt water provides an easy and refreshing means of relieving fatigue in the feet.

**Foot Powders.** Dusting powders for the feet can be very effective in relieving tiredness and keeping the feet in a healthy condition. They are absorbent powders which are able to soak up excessive perspiration, and they usually contain an antiseptic ingredient. Some also contain substances such as alum which have the effect of slightly hardening the skin of the feet and rendering it less susceptible to the effects of friction. People who suffer habitually from tired feet, or from excessive perspiration, are well advised to use a dusting powder, preferably after the feet have been bathed or washed. A good plan is to sprinkle the powder inside the sock or stocking before it is put on.

**Care of the Legs.** The cosmetic treatment of the legs consists mainly of the removal of unwanted hair. Superfluous hair can be removed from the legs without harm, but it is sometimes a lengthy and tedious process. For the various methods of removing hair, see under "Superfluous Hair."

It is not usually necessary to apply any other cosmetics to the legs when stockings are worn, but in the summer specially tinted leg creams can be used to darken the skin and give an attractive "bronzed" appearance. The various sun-tan oils and creams which are normally applied to

other parts of the body are equally useful for treating the legs.

For increasing the whiteness of the legs if this is desired, or necessary, liquid creams which contain white powders of high-covering power are available. These are similar in composition to the "wet-white" used in the theatrical profession, and are often useful for covering up the brown colour of sun-tanned legs when it is desired to do this during the early winter months.

### BATHS AND BATHING.

Bathing the body with water is one of the very oldest hygienic treatments, and it has been practised for centuries, both for cleanliness and pleasure. The building by the Romans of public baths wherever they went is well known, and some of these baths are still standing, and even in use at the present time. In many cases Roman baths were built at the site of natural springs which provided water having medicinal qualities.

A warm bath is both cleansing and stimulating, because it encourages a flow of blood to the surface of the body. A good toilet soap should always be used, and it is better to employ a large or "bath-size" tablet, because this makes the soaping of the body so much easier. The temperature of the bath water should be pleasantly warm but not hot, in order to avoid the risk of chills afterwards. For those with bath thermometers, a suitable temperature is 100-110°. Any bath should be followed by a brisk drying with a roughish towel, and a special indulgence is to follow the drying with an application of a bath dusting powder or talcum. This prevents any possible chafing of the skin and adds to the pleasure of the bathing ritual.

Cold baths have little to recommend them, apart from the psychological effect which they produce. They are not primarily intended for cleansing the body, and are often taken without the use of soap, but the plunging of the body into cold water causes an increased flow of blood to the surface, and provided the time of immersion is not too long, a cold bath can be pleasantly stimulating. For the same reasons, sea-bathing, providing it is indulged in moderately, is very beneficial.

In country districts or in houses where no fixed baths are available, a large hip-bath may be used, or if that is not possible a good substitute for a bath is to soak a large towel in very hot water, wring it out as soon as possible and wrap the body in it. Soapy water is better than plain water for this purpose, and after the body has been wrapped up for a few minutes, it should be rubbed dry with a clean towel.

**Shower or Spray Baths.** Relatively few people are able to indulge in the luxury of having a fixed shower in their bathrooms, but it is possible to have a spray fitted to any ordinary bath with hot- and cold-water taps, both taps being connected by rubber tubes to one spray, which can be directed anywhere on the body. The use of a spray or shower bath not only adds to the pleasure of the bath, but it ensures that the soapy water is thoroughly rinsed from the body before drying. Wherever possible, some kind of rinsing after bathing should always be practised. It is interesting to recall that in tropical countries where water is relatively scarce, the natives always rinse the body after bathing by pouring over it plain water from a small vessel or cup.

**Foam Baths.** Preparations have been marketed for producing foam baths in the home, but they are relatively expensive and must be used in a special way. They are usually in powder or tablet form, and are placed under the direct stream of the tap so that the force of the water assists in building up a foam. Foaming preparations for the bath cannot be used with soap, and it is therefore necessary to massage the body with the foam, using no soap at all. Foam baths taken in this way are inferior in cleansing efficiency to the ordinary soap-and-water bath, but they have a certain psychological value.

Regular foam baths are provided by establishments which specialise in medicated baths, and in these the body is completely covered by a fine

foam produced by blowing compressed air into a small quantity of foaming agent placed in the bottom of the bath.

**Bath Salts.** The purpose of bath salts is primarily to soften hard water and at the same time to give it a refreshing and attractive odour. Because of this, bath salts are in fact used in water that requires no softening. They consist of crystals of water-softening chemicals such as soda, to which have been added colour and perfume. The most costly bath salts are those which contain delicate and expensive perfumes. Sufficient bath salts should be added to the water to soften it adequately, and for the average bath a small handful of crystals is usually adequate. The crystals should be allowed to dissolve completely before one steps into the bath. Bath salts are also made in cube form, and these consist of the water-softening agent which has been powdered and then compressed. In some cases a lathering agent is incorporated in the bath salts so that an attractive foam is produced on the surface of the bath water.

**Bath Oils.** These are transparent oily liquids which nevertheless mix completely with water without separation of oily globules. Colour and perfume are incorporated, and the oils are sometimes packed in soluble gelatine capsules. The sole use of bath oils is to impart a pleasant perfume to the water and, unlike bath salts, they have no water-softening properties. Occasionally bath oils are made up in the form of emulsions which are milk-like in appearance.

**Talcum Powder.** Talcum powders are manufactured for the dual purpose of dusting the body after bathing and for local application to certain parts of the body to absorb perspiration. They are made of highly absorbent materials, and when applied to the body produce a pleasant cooling effect because they increase the rate of evaporation of moisture from the skin. The perfumes which are used in talcum powders are carefully chosen to be non-irritant and, indeed, the special talcum powders sold for use on the tender skins of babies are very often left unperfumed. Talcum powders are also useful after shaving, especially if the skin is inclined to be sensitive, and to avoid chapping in cold weather.

### PERFUMES.

The discreet use of perfume can add charm to the personality and supply an aura of pleasing freshness and appeal. The choice of perfume is largely a matter of individual taste, but the selection of a particular perfume should be made with care, having regard to time and occasion.

For day use, special types of perfume are available, and these are less concentrated and have a fresher and more delicate odour than perfumes suitable for evening wear. Lavender water and various types of Eau de Cologne are in the same class as these day-time perfumes, and are sometimes described as "toilet waters." Indeed, they can be added to the bath water as a special indulgence.

As a general rule, the lighter perfumes are more suitable for fair people than for brunettes, but in any case it is usually easy to make a successful choice of perfume from among the many tried and well-known blends produced by the leading perfumers. It is not advisable to use cheap perfume, because although the initial odour may be attractive, the inferior oils and essences used in their manufacture quickly become stale and the original odour disappears.

Toilet waters, colognes, and other day-time perfumes can be applied directly to the body, and because they have astringent properties, they are effective in reducing the flow of perspiration from areas such as the soles of the feet and the underarms. The heavier and more exotic perfumes should never be used lavishly, but should be sprayed or dabbed lightly behind the ears, on the wrists or temples, or even massaged sparingly into the hair. The warmth of the skin soon brings out the perfume and surrounds the wearer with fragrance.

As a general rule, no perfume should be applied directly to the clothing, since many of the dyes

used on textiles will dissolve in the spirit with which a perfume is compounded, and it is very easy to produce stains in this way. The sprinkling of a few drops of perfume on a handkerchief is probably the best and most effective means of using perfume regularly. A handkerchief treated with Eau de Cologne or lavender water is a most refreshing accessory to carry in hot and stuffy atmospheres.

### CARRIAGE AND DEPORTMENT.

A woman blessed with good looks and clothed in the height of fashion will never be anything more than an ordinary member of the crowd unless a graceful carriage lends her distinction. In these days, a woman with good natural deportment is comparatively rare, and there is often a tendency to shuffle along with uncertain control of the knees. A woman who knows how to walk properly strides along as if she enjoys living, unhampered by her body and feet and seemingly unconscious of her clothes. In Victorian times a good deal of attention was paid to deportment, and young ladies were taught to cultivate correct carriage by means of a heavy book carried on the head. This is still a good method, although the same effect can be achieved by remembering always to hold the head high and the chin well drawn in when walking, standing, or sitting. Special exercises, most of them of a very simple kind, have been devised for improving the carriage and, incidentally, developing the figure. Details of these can be obtained from many sources. In general, an attractive style of deportment can easily be cultivated if one remembers when walking to keep the shoulders still, the head well up, and let the movements be from the hips. The pace at which one walks should be even, with the toes pointing straight in front. One has only to study the movements of a trained mannequin to appreciate the beauty of correct posture and carriage.

### DIET AND SLIMMING.

On no account should drugs or substances sold as slimming preparations be used except under medical advice. In cases where fatness is due to over-eating, controlled dieting can obviously effect considerable improvement. Any systematic course of dieting, however, should be followed only after taking medical advice, and the doctor's instructions should be carefully followed. Many women, finding themselves growing a little stout, make the mistake of cutting down their meals to such an extent that the body receives insufficient nourishment, with the result that their general health is impaired. Exercise taken in moderation is always a good thing, but it will have no value as a slimming treatment if at the same time large quantities of starchy foods (bread, potatoes, sweets) are eaten, because these replace the calories which are expended during the exercise. As with most things, moderation is the golden rule to follow in eating, drinking, and exercise.

### CLOTHING.

**Hygienic Considerations.** The general comfort and maintenance of the body in a healthy condition depend largely on the type of clothing that is worn (see "General Hygiene," p. 821). This applies particularly, of course, to underwear, and the manufacturers and designers fully realise the importance of suitable clothing, so that it is an easy matter to obtain warm, yet healthy clothing at prices to suit all pockets. There are available fabrics in great variety, made from natural fibres such as wool, silk, and cotton, or of the newer man-made fibres, including rayons, nylon, terylene, orlon, and ardil. These all have their own special properties, and choice becomes largely a matter of preference. In many fabrics one or more fibres are blended together so as to obtain the beneficial properties of both. The general rule is to wear clothing which is as light in weight as possible, but which keeps the body adequately warm in winter and pleasantly cool in summer. All clothing should be loose, and the quality of the material is of much greater importance than quantity or number of garments. Underwear should be made of fabrics which are

easy to wash, so that frequent changes can be made.

**The Care of Clothes.** It always pays to look after one's clothes carefully in order to prolong their usefulness and to retain their original smartness and shape. If means permit, it is a good plan to avoid wearing the same dress or suit two days running, and on removing the clothes at night they should be carefully shaken or, if appropriate, brushed and put away on hangers. Washable frocks should not be allowed to get obviously soiled, but should be frequently washed, while other outer garments of heavier material, such as suits, should be dry-cleaned from time to time to restore their freshness. Clean stockings and panties should be worn each day; vests and slips changed at least twice weekly. If these garments are made of one of the many nylon fabrics that can now be obtained so easily, frequent changing and washing is a simple matter. The garments can be washed at night, and will be dry and ready to be worn again without ironing the following morning. Collars and cuffs must be spotless and changed as soon as they become soiled. Dark suits, dresses, and coats should be periodically freshened up with a clean piece of linen, wrung out in warm vinegar. This treatment should be combined with the removal of grease spots by means of carbon tetrachloride or one of the proprietary dry-cleaning solvents. Petrol and other inflammable liquids should not be used for stain removal because of the fire risk, but if nothing else is available, petrol treatment should always be given out of doors. Shiny patches and marks on outer garments can be lessened by pressing with a hot iron over a damp cloth and then gently brushing to restore the pile.

Tea, coffee, fruit juice, and wine stains should be dealt with as soon as possible, before the stain has become "set." The stained portion of the garment should be soaked or sponged with cold water. Never plunge stained articles into hot water, as some stains are permanently fixed by this treatment. Ink spots can sometimes be removed by treatment with oxalic acid or salts of lemon, but since both these substances are poisonous, they should be used with care.

Shoes will last longer if the soles and heels are repaired before they are worn right down. Regular polishing with cream or wax will help to preserve the leather, or in the case of suede shoes, regular brushing with a specially designed brush will preserve the appearance.

**Storage of Clothes.** All washable clothing should be washed, ironed, and thoroughly dried before being stowed away in drawers or cupboards. Delicate white silks should be wrapped in blue or opaque paper to exclude the light and to prevent yellowing if they are likely to be stored for a long time.

Outer garments, especially those made of wool, should be thoroughly brushed, and if possible enclosed in paper or cellophane for protection against moths. If no such protection is given, the clothes should be taken from the wardrobe periodically and given a good shaking and brushing to make sure that any moth eggs and grubs are removed. Fur coats should be similarly cared for, and if they are of especial value it pays to have them put in a cold store during the summer months. Most reputable furriers provide such a service at relatively low cost.

Woolen or silk articles stored in drawers can easily be damaged by moth grubs unless precautions are taken. One of the proprietary anti-moth preparations should be used, or some crystals of paradichlorobenzene can be sprinkled amongst them. This substance will kill not only live moths and their grubs but also the eggs.

### DIET AND A HEALTHY SKIN.

The importance of a generally healthy body in maintaining skin health has already been mentioned. Nevertheless, it is a mistake to assume that perfect health automatically ensures a beautiful skin. The porcelain-like complexion of many tuberculosis patients and the spotty faces of vigorous adolescents contradict this belief. On

the other hand, deficiencies or excesses in the diet sometimes show themselves on the skin before their effects are apparent in other organs of the body. This is also true of people who are allergic (abnormally sensitive) to certain foodstuffs, such as eggs, tomatoes, strawberries, shellfish, etc. The first adverse reaction in such cases is nearly always an eruption of the skin; in other words, the condition of the skin gives the first and sometimes the only warning that there is something wrong with the normal working of the body. This is also true in many cases of food poisoning, the first symptom of which is often a well-defined skin rash.

It is often said that failure to eliminate waste matter from the body regularly and completely is likely to show itself in the appearance of the skin and that people who are "constipated" will almost certainly have muddy complexions and be susceptible to pimples and acne. There is, however, little medical evidence to support this view. Constipation may be due to a very large number of causes, some of them serious, and if the degree of constipation is marked, medical advice should be obtained. The habitual use of laxatives and purgatives is to be deplored, and indeed it is preferable to be slightly constipated than always to have loose motions.

**The Choice of Diet.** In general, it can be said that, provided the diet is varied and well balanced, there is no need to worry about such things as vitamins, neither is ill-health likely to be caused by deficiencies in the diet or its unsuitability. The following foods, eaten regularly and in moderation, will ensure ample variety and balance in the diet: meat or fish or both; eggs, raw or cooked; green vegetables, including raw salads; other vegetables, especially carrots; fresh fruits; butter or margarine, or both; milk, either liquid or in the form of milk puddings, blanc-manges, custards, etc.; bread and/or other cereals. All of these, of course, need not be eaten daily or even weekly, but meals should be arranged so that too much of one kind of food is not eaten to the regular exclusion of others on the list.

The quantity of food eaten obviously depends upon such things as the size and weight of the individual and their degree of activity and expenditure of physical energy in the course of their daily work. No rules can be given, except the one that applies to so many things, and that is to observe moderation. There is a good deal of sound advice in the words of the old music-hall song "A little of what you fancy does you good," provided, of course, that you know from experience what foods, if any, must be particularly avoided.

Special or fancy diets, such as the "Oslo Breakfast" or the "Hay Diet," which have been claimed to preserve and improve both health and figure, should not be followed without medical guidance, for excessive fatness and weight-gain can be due to causes other than over-eating (see *Diet and Slimming*).

**Alcoholic Drinks and the Skin.** The effect of alcohol in the diet is to cause an increase in the flow of perspiration, and hence in the rate at which heat is lost from the body. This is accompanied by a rush of blood to the tiny vessels below the skin surface (capillaries) so that they become enlarged and produce a visible reddening or flushing of the skin. If this enlargement takes place regularly and excessively some of the capillaries may be ruptured, producing the red-veined noses and cheeks that are popularly associated with immoderate addiction to alcohol. Alcoholic drinks, however, are not the only possible cause of such conditions. Where skin diseases of any kind are present, alcoholic beverages are best avoided (together with excessive quantities of strong tea and coffee), but the advice of the doctor will naturally be followed in such cases.

When the body and skin are normally healthy, alcoholic drinks in moderation are not deleterious in any way. Apart from their social value, they may stimulate the gastric juices and thus improve the appetite and digestion. The rule of drinking in moderation applies especially to spirits, which should be well diluted, except when taken in small quantities and sipped slowly, as in the case of cocktails and liqueurs.

## GLOSSARY OF HYGIENE AND BEAUTY PREPARATIONS.

**After-shave Cream (Lotion).** Preparations to cool and soothe the skin after shaving. The cream is a simple emollient one, semi-greasy, and slightly perfumed. The lotion is astringent (q.v.) and often contains an antiseptic. Both cream and lotion may also be mentholated.

**All-purpose Cream.** An emulsion (q.v.) cream less greasy than a cold cream but more so than a vanishing cream. It can be used sparingly as a foundation and more lavishly as a night, massage, or cleansing cream.

**Antiseptic.** A substance which prevents the growth (multiplication) of germs or bacteria without actually killing them (see "Disinfectant," "Germicide").

**Anti-wrinkle Preparations.** Creams, oils, and lotions designed to keep the outer horny layer of the skin soft and supple. Applied with massage, they can delay the onset of wrinkles and improve the appearance of already wrinkled or elderly skin.

**Astringent.** A liquid or cream which has a tonic or freshening effect when applied to the skin and which is often used to "close the pores." Witch-hazel extract is a commonly used astringent; alum is a more powerful one.

**Baby Powder.** The most widely used of all baby preparations. A soothing absorbent powder, generally and preferably unperfumed. A powder prepared by a reputable manufacturer should be used, since "home-made" mixtures of fuller's earth, boracic, etc., are seldom sterile, and may cause serious harm.

**Barrier Creams.** Creams used industrially and in the home to protect the hands; they must always be well rubbed into the skin (especially the nails) before starting work. Of two main types, the water-resistant barrier creams give protection during "wet" jobs, such as washing-up, vegetable preparation, and house cleaning, while the oil-resistant creams protect the hands during gardening, cleaning the car or bicycle, etc.

**Bath Essences.** A perfume of a light type for imparting a pleasant fragrance to the bath water. Eau de Cologne and lavender water can be used as bath essences, in addition to preparations specially compounded for this purpose.

**Bath Salts.** Water-softening chemicals in crystal or powder form suitably perfumed and coloured. They should be dissolved completely in the water before taking a bath, in order to enable them to exert their water-softening action.

**Bleaching Creams.** Creams containing special ingredients which have a bleaching action on the colouring matter of the skin. They are intended for the removal of unwanted sun-tan, and sometimes freckles can be made less obvious by the application of such creams. They should, however, be used with caution, and it is generally preferable to lighten the skin by means of a powder cream of fairly high covering power.

**Brilliantine.** An oily hair dressing whose main function is to impart a gloss to the hair. Brilliantines are of two types, one of which, described as non-separable, consists of light mineral oil, perfumed and sometimes coloured, while the other, or separable, is a mixture of oil and spirit. The latter type must be well shaken before use. The separable brilliantines are especially suitable for thin hair, which is usually easily kept in place. The non-separable brilliantines are better for people with dry hair, and they have greater fixative properties than the other type.

**Brushless Shaving-cream.** A cream in emulsion form which is applied directly to the face after washing and which acts as a lubricant for the razor during shaving. In America more men use brushless creams than any other type of shaving preparation, and they are consistently becoming more popular in this country.

**Cake Make-up.** Foundation preparation made in the form of a solid block or cake, and often applied by means of a moistened sponge or pad. Cake make-up can take the place of both foundation cream and powder, but many people prefer to add a dusting of powder on top of the cake make-up. They are not very satisfactory for women with dry skins.

**Calamine.** Calamine is a preparation of zinc in powder form which is generally used as a lotion for the relief of sun-burn. It is also a main constituent of baby powders, but because of the susceptibility of burnt or irritated skin to infection, calamine preparations should also contain an antiseptic.

**Chignon.** An additional coil or plait of hair dressed into a flat circle, cone, or bun, usually attached to the hair of the nape of the neck. Worn in this way, it may be found a practical hair style when a permanent wave has almost grown out and a new one has not been given.

**Cleansing Preparations.** Cosmetics in the form of cream, lotion, or milk intended for cleansing the skin as a basis for make-up. Cleansing creams are soft and greasy in character, and after being well rubbed into the skin the surplus is wiped off with tissue, when much of the surface dirt will be removed with it. Cleansing milks and lotions are less greasy in character, and are designed for use on skins which are naturally greasy.

**Cold Cream.** One of the earliest types of cosmetic cream. It was originally made from a mixture of pure lard and rose-water, and produced a cooling sensation when applied to the skin—hence its name. Modern cold creams are generally described under some other name such as “night cream” (*q.v.*) or “cleansing cream”, and are commonly applied last thing at night and left on the face until the next morning. Dry-skinned people can use cold cream sparingly applied as a foundation for make-up.

**Cold Wave.** A chemical means of softening the hair while it is tightly wound on curlers and then hardening it again so that it retains its curls as a permanent wave. The outfits supplied for permanently waving the hair at home are all of the cold-wave type.

**Cologne.** The original Eau de Cologne was a blend of various aromatic oils diluted with pure spirit. Modern manufacturers have produced variations of the original cologne which have characteristic perfumes of their own. The name “cologne” is sometimes applied to any light perfume with a fresh, flowery odour.

**Complexion Milk.** A lotion in emulsion form for cleansing the skin prior to make-up (see “Cleansing Preparations”).

**Cuticle Cream.** A preparation containing alkali for softening and removing the dead skin around the curves of the nails (see “Cuticle Remover”).

**Cuticle Remover.** A solution of caustic potash mixed with glycerine and suitably perfumed for softening and removing the cuticle around the nail. Its use contributes substantially to the well-kept and neat appearance of the nails.

**Dentifrices.** Any preparation for cleaning and polishing the teeth. In common parlance, the term “dentifrice” is applied more especially to the block form of tooth cleanser which is rubbed off on to the moistened toothbrush. This type is probably the most economical form of dentifrice.

**Denture Cleaner.** A powder for dissolving in water to form a bath in which artificial teeth can be left to soak. Denture cleaners usually contain oxygen-producing substances which remove the stains from the dentures, as well as traces of food particles and film. Dentures should be soaked for at least 20 minutes, and preferably overnight.

**Deodorants.** These are preparations for reducing or eliminating the unpleasant odour of

stale perspiration from the body. They are of two types—those which contain very powerful astringents and diminish the flow of perspiration and those which merely mask the perspiration odour. Deodorants are available in four forms, liquids, creams, sticks, and powders. The most effective of these are the ones which contain powerful astringents, especially aluminium compounds. They should, however, be used in moderation, as while perfectly safe when applied at intervals of a few days, they may cause skin irritation if used more frequently. Many deodorant preparations, especially those in powder form, contain antiseptic substances which do not affect the flow of perspiration but remove its odour.

**Depilatory.** Any material designed to remove hair from the skin surface. Chemical depilatories in liquid or cream form are the easiest and most effective to use, but can irritate the skin if applied too frequently. The hair of the legs is often removed by rubbing with an abrasive block, and there are also wax depilatories, by the use of which the hairs are pulled out by brute force. Chemical depilatories should never be used on the face, and superfluous hair here is best treated by a trained expert.

**Detergent.** The word “detergent” literally means any substance capable of cleansing and removing dirt. In recent times it has come to be applied more particularly to household cleaning agents which do not contain soap as an active ingredient.

**Disinfectant.** Literally, a material which destroys or removes infection. Another name for a germicide (*q.v.*).

**Dry Shampoo.** Of two types, depending upon whether they are used by men or by women. A dry shampoo for men's use is a solution of soap in spirit which enables a lather to be produced on the dry hair and removed by sponging with a minimum use of water. For women's use a dry shampoo is an absorbent powder which is rubbed into the hair and then brushed out again, carrying much of the dirt and grease with it. It is intended for occasional use when the normal wet shampoo is not practicable.

**Dusting Powder.** A powder made of absorbent materials for completely drying the skin after washing. Dusting powder includes both baby powders and talcum powders (*q.v.*).

**Emulsion.** The intimate mixture of an oily substance with a watery one. Oil and water do not normally mix, but if certain substances known as “emulsifying agents” are present, the two can be made to blend together. Common examples of emulsions are milk and salad cream.

**Eyebrow Pencil.** Eyebrow cosmetic in stick form like thin crayons or in the usual pencil style encased in wood. In the latter form they are stronger and more easily applied. They are used for modifying the outline of the eyebrows, especially after plucking, and are obtainable in various shades of brown as well as black.

**Eye Shadow.** Generally a cream with a greasy base containing blue, green, or brown colouring material. They are applied to the upper eyelids, and are more particularly suitable for evening wear.

**Face Pack.** Sometimes called face masks. They are usually in powder form which is mixed to a paste with warm water before use. They produce a sensation of warmth and tightening which gives the impression that something beneficial is happening to the skin. Some face packs contain astringents and bleaching agents, but their main value is in the absorption of impurities from the skin and the removal of surface debris. Their main ingredient is an absorbent earth, such as kaolin or fuller's earth.

**Face Powder.** Tinted and perfumed powder designed to give a pleasing matt finish to the skin. These powders can be made to give high covering

power, in which case they are very opaque, or they can be translucent and therefore less obvious when applied. These latter are generally described as "fine" powders, a description which has no relation whatever to the particle size of the ingredients.

**Foot Powder.** A dusting or talcum powder especially prepared for use on the feet, it generally contains an antiseptic ingredient with deodorant properties, and may also be formulated to harden the sole of the foot slightly.

**Foundation Cream.** A cream whose main purpose is to form a sticky layer on the skin to which face powder will adhere. Foundation creams can be of the non-greasy type, in which case they are especially suitable for greasy-skinned subjects, or of the greasy type for dry-skinned people. Foundation creams should always be applied on a clean skin, and a fresh application should not be made without first washing off all the old make-up. The non-greasy type of foundation cream is also known as vanishing cream (*q.v.*), because when rubbed into the skin it is scarcely visible.

**Germicide.** A substance which is capable of killing germs or bacteria outright and not merely, like an antiseptic, preventing their growth. Apart from fire, there is no germicide which will kill all types of germs, and different germicidal substances are therefore employed for different purposes, according to the kind of germs that have to be attacked.

**Hair Bleach.** A preparation for destroying some or all of the natural colouring matter of the hair. Perhaps the most commonly used is ordinary peroxide of hydrogen, but there are proprietary bleaches which are safer and easier to apply. The bleaching of dark-coloured hair should always be carried out in stages, giving a comparatively weak treatment each time. The application of strong bleach to the hair will weaken it, and may cause serious damage.

**Hair Cream.** A dressing for the hair used almost exclusively by men. Some hair creams are merely fixatives and contain gummy substances which keep the hair in place, while other hair creams contain large quantities of oil, and besides fixing the hair, they impart an attractive gloss, similar to that produced by brillantines.

**Hair Dye.** There are many different types of dye for altering the existing shade of hair, or for restoring white hair to its normal colour. The chief varieties are the various forms of henna and the so-called "oxidation dyes," which require considerable skill in their application, and they should therefore be applied by a professional hairdresser. Oxidation dyes are available in a wide variety of colours, including some not found naturally on the hair.

**Hair Fixative.** The name given to a gummy dressing for the hair, the main function of which is to keep the hair in place. Fixatives are normally used only by men, and they may be compounded with or without oil, the latter type being more suitable for people with greasy hair.

**Hair Lacquer.** Setting lotions which are thin enough to be capable of being sprayed. They can be made up with water or with spirit, the latter having a much quicker drying time than the former. They are particularly useful for keeping an elaborate hair style in place for a special occasion or for retaining obstinate "ends" in position.

**Hair Rinse.** A preparation usually in the form of crystals to dissolve in water for use as a final rinse after shampooing the hair. The purpose is to counteract the dulling effect of some soap shampoos in hard water and to give a slight crispy feeling to the hair. Special rinses are not required with soapless shampoos.

**Hair Tint.** Sometimes used synonymously with hair dye (*q.v.*), but generally taken to mean a preparation for imparting extra brightness to the hair or adding just a little colour. Some tints,

especially those based on henna or camomile, are incorporated in shampoos.

**Hand Cream.** A bland cream for soothing and softening the hands, especially after the skin has become dried and roughened through long immersion in water or by exposure to the weather.

**Hand Jelly.** Used in the same way as a hand cream, but less greasy in character. Hand jellies generally contain a considerable proportion of glycerine, and are the modern successor to the simple glycerine and rose-water mixture so popular many years ago.

**Hormone Cream.** Creams containing one or more of the sex hormones, the theory being that after about the age of 30, the manufacture of these hormones by the body practically ceases, thereby hastening the ageing of the skin and the onset of wrinkles. The use of hormone creams is not without risk, and expert medical advice should be sought before they are used to any considerable extent.

**Iron Wave.** The wave produced in straight hair by compressing it between the heated tongs of a specially designed waving-iron. The waving is more effective if the hair is slightly damp, but the repeated application of hot irons to the hair is apt to make it become excessively dry and brittle.

**Lip Salve.** A colourless or lightly tinted greasy preparation in stick form for protecting the lips against chapping and for promoting the healing of already chapped or cracked lips. Lip salves are usually softer and more greasy than lipsticks.

**Lipsticks.** A greasy cream in stick form for covering the lips. Lipsticks are made in a wide variety of shades, which vary with fashion and which should be selected to suit the general colouring, style of dress, etc., of the wearer. Some lipsticks are claimed to be kiss-proof, but this is a relative term, and a really permanent lipstick has yet to be devised.

**Liquefying Cream.** Usually a cleansing cream or one intended for night use which is made from a blend of oils and waxes of low melting point, so that the warmth of the skin is sufficient to liquefy the cream when it is applied.

**Liquid Foundation.** A suspension of face powder in a watery solution which sometimes also contains emulsified oil. Designed specially for women with greasy skins, a liquid foundation provides a less oily base than a foundation in cream form.

**Marcel Wave.** A system of producing temporary waves and curls in the hair by heated irons, and named after its originator, the French hairdresser Marcel.

**Mascara.** An eyelash cosmetic for darkening and increasing the apparent length of the eyelashes. The most popular type is in block form, and is applied by a special brush moistened with water and rubbed over the surface of the block. More permanent types are made with a greasy base, which is slightly warmed and applied with a fine brush.

**Medicated Soap.** Fine toilet soap containing a medicament such as sulphur or an antiseptic ingredient, used for treating affections of the skin. Medicated soaps should be used only on doctor's instructions.

**Mouth Wash.** An antiseptic solution for rinsing the mouth after meals, and of especial value when septic conditions are present, as after the extraction of teeth or in cases of gum infections.

**Nail Polish.** A fine abrasive powder which is applied to the nail and then polished with a chamol-leather pad. Other types of nail polish are waxy in character and are made in the form of pencils.

**Nail Varnish.** Sometimes referred to as nail lacquer. These are cellulose lacquers similar to those used for metalwork and other surfaces but containing pigments to give a wide variety of shades. Nail varnishes are specially formulated to have extra rapid drying properties.

**Nail-varnish Remover.** A liquid solvent which will dissolve the dried film of varnish and enable it to be wiped off the nail. In place of the proprietary nail-varnish removers, solvents such as acetone or amyl acetate can be used, and these are obtainable from any chemist.

**Nail Whitener.** A paste or cream incorporating a white pigment for producing an even opaque white edge to the nails. Nail white is also available in pencil form, which is simpler to apply than the creams.

**Night Cream.** A greasy cream for applying to the face and leaving all night. Many cold creams and liquefying creams (*q.v.*) can be used as night creams.

**Oil Shampoo.** A shampoo in the form of a thick liquid which is applied to the unwetted hair and which produces little or no lather. Oil shampoos are specially suitable for women with dry or brittle hair because they have a conditioning effect.

**Perfume.** The name perfume is usually applied to a compounded blend of flowery oils and other aromatic substances dissolved in spirit.

**Permanent Wave.** A wave or curl produced in the hair by softening it, moulding it into shape around curlers, and allowing it to become hard again. In hot waving the softening is achieved by the combined action of an alkaline lotion and heat, while in cold waving (*q.v.*) the hair is softened by special chemicals.

**Postiche.** The hairdresser's name for a wig or for made-up artificial hair used on dummies and to demonstrate hair styles.

**Powder Cream.** A blend of face powder and vanishing or foundation cream which produces an even matt appearance when applied to the skin. A subsequent application of powder can be given if desired.

**Pre-shave Lotion.** A spirit preparation often containing a small quantity of resinous material which is designed partly to protect the skin during shaving and partly to make the hairs more easy to cut by the razor. These lotions have been especially recommended for use in conjunction with dry-shaving machines.

**Rouge.** Pigments in various pink and red shades made up as powder blocks or cream. The judicious use of rouge can considerably improve sallow or pale complexions.

**Setting Lotion.** A liquid for application to the wet hair after rough towelling following a shampoo, which enables the hair to be dried more rapidly and to be combed and set more easily. The use of a setting lotion also helps to keep the hair style in place.

**Shampoo.** Any preparation for washing the hair. Available in powder, liquid, and cream form, and made of either soap or soapless lathering ingredients.

**Shampoo Rinse.** A special rinse for the hair, often incorporated in a packet of soap shampoo (see "Hair Rinse").

**Shaving.** Comfort in shaving depends in the first place on the softening of the beard. Water, preferably warm or hot, is the best for this purpose, but it needs to be in contact with the face for about two minutes.

All good shaving preparations retain moisture in the lather and thereby assist in softening the beard as well as lubricating the passage of the razor over the face.

**Shaving Soap.** A highly refined soap similar to toilet soap but specially formulated to produce a close, dense lather which does not break down during the process of shaving. Available as sticks, bowls, or cream.

**Skin Food.** The name given to creams or lotions for softening the skin and keeping it supple. They "feed" the skin only in the sense that leather or a cricket bat can be "fed" with oil. The real food of the skin comes from the blood stream.

**Skin Tonic.** Generally a lotion containing some spirit or other mild astringent for use after a cleansing cream or massage and for "closing the pores."

**Sun-tan Cream.** Creams designed to protect the skin against excessive sunburn by filtering out some of the heat rays. Such creams can also contain brown colouring matter to stain the skin and enable a tanned appearance to be gained more rapidly. Similar preparations are made in the form of oils.

**Talcum Powder.** A perfumed absorbent powder, the main ingredient of which is very often talc or French chalk, used for dusting the skin (see "Dusting Powder").

**Toilet Soap.** Soap made from highly refined raw materials and containing no trace of irritant substances. Toilet soaps are more concentrated than household soaps, and can be obtained in a wide range of perfumes and colours. The price largely depends on the quality of the perfume that is used.

Pears Transparent is a toilet soap made by a special process, and is of extreme purity and mildness.

**Toilet Water.** A generic name which includes light perfumes, such as Eau de Cologne, lavender water, and the so-called day-time perfumes.

**Toothpaste.** A dentifrice (*q.v.*) in paste form containing a polishing material and a cleaning agent which usually lathers. Some toothpastes contain specific ingredients for which special claims are made.

**Tooth Powder.** Dentifrice in powder form containing the same ingredients as toothpaste, but more concentrated because of the absence of water.

**Vanishing Cream.** A foundation cream of a non-greasy character which is invisible when applied to the skin.

**Vitamin Cream.** Foundation or cold creams containing extracts of the fat soluble vitamins, usually vitamin A. The value of vitamins in toilet preparations has, however, yet to be proved.

# Cookery and Household Hints

By "Good Housekeeping Institute"

## I. COOKING EQUIPMENT

Soundly constructed and well-designed cooking-utensils add immeasurably to the pleasure and ease of cooking. Careful and selective buying is well worth the trouble, and should result in a well-equipped cupboard that does not require constant replacements. The following points are among those to be observed:

1. Good cooking-utensils should be easy to clean. Look for a smooth interior, but avoid one that is too highly polished, as foods tend to stick and burn on an excessively high finish. Lids should fit well and be free from crevices.

2. Examine the handles to see that they are firmly fixed and sufficiently insulated to stay cool when in use.

3. Sharp angles where the base and sides meet are to be avoided, as they make cleaning difficult.

4. For cooking on solid electric or other flat hot plates utensils must have a reasonably heavy machined base to ensure quick transfer of heat and eliminate waste. For non-solid plates thinner gauge pans are suitable, though too lightly made ones should be avoided, as they soon tend to lose their shape.

5. Avoid buying unnecessary gadgets without being certain of their ultimate usefulness. They should be easy to store and clean, and should be simple and effective to use.

### SPECIALISED COOKING-UTENSILS

**Pressure Cookers.**—These are becoming increasingly popular, largely because of the time and fuel they save. Pressure cookers are specially constructed pans, usually of aluminium, with a special fitting lid, a pressure weight, or spring-loaded valve, and some type of safety device. The modern pan type is reasonably light and simple to handle. Manufacturers' instructions for cooking must be followed closely, and when buying a cooker the choice should lie between those of reliable manufacture which have passed standard tests. The size should be chosen according to the number in family, and the cooker must have a base suitable for the type of hot-plate or burner on which it will be used.

**Steamers.**—For large households the tiered steamer is a most useful item of kitchen equipment. As a rule there are three separate pans which fit on top of each other over a base pan. One or more tiers can be used at a time, and the steam to each compartment can be separately controlled. Aluminium is the most suitable metal for this type of pan, and the handles and knobs should, of course, be insulated.

A simpler steamer, for small households, is a pan with a perforated base designed to fit over another saucepan. These are usually aluminium or enamel, and should have a well-fitting lid.

**Preserving-pan.**—Fairly heavy gauge aluminium is a good choice for a preserving-pan. It should have a fairly wide top to allow for the necessary evaporation during jam-making. The handles must be sturdy. Tinned copper pans are also satisfactory. Unlined brass and copper pans are suitable for jam-making only, and must be avoided for pickles and chutney, as vinegar reacts with them to form traces of a poisonous salt.

**Electric Mixers.**—A good electric mixer can save considerable time and energy, especially in large households. A reliable machine that is easy to operate and simple to adjust is essential.

Most electric mixers are primarily designed for making cakes and puddings, and for all whisking processes. Some have attachments for mincing, coffee-grinding, grating, blending, liquidising, juice extracting, dough-making, potato peeling, etc. Success in using a mixer depends largely on the careful following of directions. Best use can be obtained from a mixer if it has a permanent position in the kitchen where it can always be ready for use.

**Knives.**—It is really essential to have a good set of cooking-knives—

**Vegetable Knife.**—A small pointed knife with a blade 3 to 4 inches long. Some types have a serrated edge, and these are useful for slicing purposes.

**Cook's or French Knife.**—This knife is used for cutting up and chopping food, and has either a long or medium blade tapering to a sharp point.

**Round-ended Knife.**—A general-purpose tool.

**Carving Knife.**—There are various different shapes and sizes of carving-knives. For ordinary joints a knife with a long and fairly broad blade, slightly curved and sharply pointed, is satisfactory. For game and poultry, a pointed knife with a shorter blade is necessary. For ham, tongue, etc., a long, thin, even-bladed knife without a pointed end is usually preferred.

### CARE OF COOKING UTENSILS

**Aluminium Saucepans.**—Wash in hot water using a stiff brush. Avoid using scratchy abrasives and soda, even if the pan is discoloured. This typical discoloration is quite harmless, and is due to traces of iron in the water or commercial metal. It can be removed, if desired, by boiling water with a weak acid, such as vinegar or fruit parings, in the saucepan. The outside of aluminium pans can be polished with fine dry steel wool.

**Baking-tins.**—Wash in hot soapy water, rinse and dry in a warm oven, or on the rack of a closed stove. Discoloured greasy tins should be stewed for an hour in water to which soda has been added in the proportion of 1 oz. to 1 gallon.

**Casseroles.**—Steep earthenware casseroles in cold water and then wash in hot soapy water, using a stiff brush.

**Enamel Ware.**—Soak immediately in cold water, and clean in hot soapy water. Salt can be used to remove any stains, but scratchy abrasives must be avoided, as they damage the surface.

**Frying and Omelet Pans.**—Pour off any grease and wipe the pan with a pad of absorbent paper. Wash only occasionally. New pans which are inclined to stick should be heated with a little fat. Remove from the heat and add a handful of salt. Wipe round vigorously with an old cloth or paper. Do not repeat this treatment too often, or the surface of the pan will be damaged.

**Glass Ovenware.**—Soak in cold water. Wash in hot water and soapless detergent, using a pad of fine steel wool or a cloth dipped in borax to remove any obstinate stains. Rinse well.

**Kettles.**—In hard-water districts kettles need to be de-furred occasionally. Pour in a little vinegar, heat slightly, and leave to stand for an hour or two, when it will be easy to remove the fur. Rinse very thoroughly before using again.

**Mincer.**—Take to pieces and remove all scraps of food, using a skewer if necessary. Wash in hot, soapy water, rinse and leave in a warm place to dry thoroughly. Reassemble before putting away.

### EQUIPMENT REQUIREMENTS

The following is a comprehensive list of cooking-utensils sufficient for two people setting up house. Those considered essential are marked with an asterisk.

**Saucepans and Kettles, etc.**

\*6 saucepans (assorted sizes: 2 large, 2 medium, and 2 small)

Double boiler

3-tiered steamer

\*1 shallow frying-pan

Deep-fat pan and basket

\*2 kettles (1 large, 1 small)

Pressure saucepan or cooker (optional)

**Baking-tins, etc.**

- \*12 patty pans (or 2 sets bun tins)
- 2 sandwich tins
- 2 pie plates
- \*Baking-sheets
- Swiss-roll tin
- Flan ring
- \*Set of pastry cutters
- \*3-4 cake tins (assorted sizes)
- 2 wire cake-trays
- \*Meat tin
- \*Trivet for meat

**Utensils for Food Preparation**

- \*Colander
- \*Whisk
- Grater and shredder
- Potato masher
- \*Pointed strainer
- Lemon squeezer
- Funnel
- \*Pastry Board
- \*Rolling-pin
- \*Flour dredger
- \*Pastry brush
- Salad shaker
- \*Fish slice
- \*Graduated measure
- \* $\frac{1}{2}$ -,  $\frac{1}{4}$ -, and 1-pint measures or one graduated measure
- Standard measuring-cups and spoons
- \*Mincer
- Hair sieve
- Wire sieve

**\*Chopping-board**

Vegetable and icing forcing pipes

**Cutlery and Small Tools**

- \*Set of kitchen knives (round-edged, cook's, vegetable, palette, and saw-edged)
- \*3 or 4 forks (large, small, and two-pronged)
- \*2 or 3 wooden spoons (assorted sizes)
- \*Kitchen spoons (cook's, perforated, scoop)
- \*Potato-peeler
- Apple-corer
- Bottle-opener
- Tin-opener
- \*Kitchen scissors
- \*Knife-sharpener

**China, Heatproof Ware or Enamel**

- \*Mixing bowl
- \*4 pudding basins (assorted sizes)
- \*2 or 3 pie dishes (assorted sizes)
- \*2 or 3 casseroles (1 will suffice at first)
- \*3 or 4 plates
- \*3 or 4 jugs
- 1 soufflé case
- \*2 jelly moulds (1 will suffice at first)

**Other Equipment**

- \*Kitchen scales
- \*Store jars and containers
- \*Bread bin
- Sugar thermometer
- \*Flour bin
- \*Cake and biscuit tins
- Preserving-pan
- Small refuse bin

**II. BASIC COOKERY METHODS****BAKING**

This is a method of cooking foods by dry heat in the oven. It is a suitable way of cooking many foods, and nutritive loss other than that of Vitamin C is low. Times and temperatures, of course, require to be regulated according to the type of food.

**Vegetables**

Not all vegetables bake satisfactorily, as a moist heat is often required to soften the cellulose. The following, however, bake well, although (with the exception of potatoes) it is necessary to add a little fat, milk, or water to provide some moisture—potatoes, carrots, parsnips, turnips, Jerusalem artichokes, onions, and marrow. Beetroot bake extremely well when placed in a greased casserole and cooked until tender at about 300° F. Peel and serve hot or cold, either sliced or diced.

**Times for Baking Vegetables.**—*Potatoes.*— $\frac{1}{2}$ – $1\frac{1}{2}$  hours, according to size.

*Artichokes and Parsnips.*—1 hour.

*Onions.*— $\frac{1}{2}$ –1 hour.

*Beetroots.*—1–2 hours.

*Macedoine in Stock.*— $\frac{1}{2}$ –1 hour.

**Fruit**

Most fruits can be baked very successfully, with the addition of a little water to prevent shrivelling. Cook slowly in a covered dish, and at the start of cooking add sugar to taste.

**Meat**

Meat baked in the oven is usually referred to as roasted, see p. 840.

**Fish**

This is a very suitable way of cooking fish. The fish should be weighed and wiped, and then placed in a greased fireproof dish. Sprinkle with salt, pepper, a little lemon juice, and then add a little milk or water. Dab with shavings of butter or margarine and cover with greaseproof paper.

The temperature required for baking fish is about 400° F. Allow 6–10 minutes to the pound and 6–10 minutes over, according to the thickness. Thin fillets take about 15 minutes. When the fish is cooked the flesh will appear white and firm, and will come away easily from the bone. A curd forms between the bone and the flesh.

Whole fish or round outlets such as hake or cod can be stuffed before baking. The stuffing is placed in a cavity where the entrails have been removed. In the case of whole fish, the scales and eyes should be removed, but the head left. For plaice, sole, etc., using a sharp knife cut the flesh right down the back bone and loosen it away from the bone as far as the fin. Place the stuffing in the cavity.

A suitable stuffing is forcemeat, see p. 858. Garnish with tomato, lemon slices, fennel, olives, or grapes, serve with parsley, fennel, egg, or anchovy sauce.

**Cakes and Pastry**

These are practically always cooked by baking. Times vary according to type and size of cake or pastry involved. It is important not to disturb cakes or pastry by opening the oven door too often while cooking. The following table will serve as a general baking guide:

Cakes, etc.	Temperature.	Time.
<b>Plain Cakes:</b>		
Small (e.g., Rock Cakes) . . . . .	Hot (450–475° F.)	10–15 minutes
Large . . . . .	Moderately hot (400° F.) lowering to Moderate (350° F.)	Approx. 1 hour per 1 lb. of mixture (varying with depth of tin)
<b>Rich Cakes:</b>		
Small (e.g., Queen Cakes). . . . .	Moderately hot (400° F.)	15–20 minutes
Sandwich Cake . . . . .	Moderately hot (375° F.)	30–40 minutes (depending on depth)
Large (e.g., Madeira) . . . . .	Moderate (350–375° F.)	Approx. 1 hour per 1 lb. (varying with depth of tin)
Large (e.g., Fruit) . . . . .	Moderate (325–350° F.)	1– $1\frac{1}{2}$ hours per 1 lb. of mixture (according to amount of fruit)
<b>Scones</b> . . . . .	Very hot (475° F.)	8–10 minutes
<b>Biscuits</b> . . . . .	Moderately hot (400° F.)	15–20 minutes

## TEMPERATURES AND TIMES FOR BAKING PASTRY

Type of pastry and dish.	Temperature.	Time.
<i>Shortcrust:</i>		
Fruit pies . . . . .	425-475° F.	35-40 minutes
Jam tarts . . . . .	450-500° F.	10-15 minutes
Cornish pasties (with cooked meat) . . . . .	450-500° F.	30-40 minutes
<i>Flaky Pastry:</i>		
Meat pies (with cooked filling) . . . . .	425-475° F.	30-40 minutes
Patties . . . . .	475-500° F.	10-20 minutes
<i>Puff and Rough Puff:</i>		
Flan cases . . . . .	475-500° F.	10-20 minutes
<i>Choux Pastry:</i>		
Eclairs . . . . .	450-475° F.	30-40 minutes
<i>Potato Pastry:</i>		
Vegetable pies . . . . .	450-500° F.	30-40 minutes
<i>Hot-water Crust:</i>		
Pork pies . . . . .	350-400° F.	1 hour
<i>Suet Pastry:</i>		
Jam roll . . . . .	350-400° F.	1-1½ hours

For recipes and methods of making each see pp. 858-61.

## BOILING

The essence of boiling is the immersion of food in boiling water, and it is the simplest process in all cookery. In actual fact many so-called boiled foods are cooked at slightly below boiling point (212° F.) and are, therefore, strictly speaking stewed or simmered.

## Boiled Meat and Poultry

Weigh the joint, wash or wipe it, and then tie or truss it according to type. Plunge into boiling salted water, having just sufficient water to cover the joint. Boil rapidly for about 5 minutes, and then reduce the heat and maintain the water at simmering point until the meat is cooked.

The preliminary fast boiling coagulates and sets the proteins so that a casing is formed, and the flavour and some of the juices are retained in the joint. Fast boiling must not be prolonged over the five minutes, or shrinkage and toughness will result. Simmering temperature is indicated by gentle bubbles rising up the side of the pan.

Vegetables and herbs can be added to the water for flavour. Salt meat should be soaked for several hours before cooking. Place it in cold water and bring slowly to the boil, skim and simmer the required time. Ham and bacon which is to be served cold should be cooled in the liquor.

**Joints of Meat Suitable for Boiling.**—*Beef.*—Brisket (fresh or salted), silverside (salted), flank, ox tongue.

*Pork.*—Leg, loin, best end of neck, belly (salted), hand and spring, head (fresh or salted), tongue and brains.

*Lamb or Mutton.*—Leg, breast, tongue, brains.

*Veal, Calves' feet.*

*Ham and Bacon.*

*Fowls.*

**Times for Cooking.**—For fresh meats allow 20 minutes to the lb. and 20 minutes over; for salt meats allow 25 minutes to the lb. and 25 minutes over.

A young fowl should be boiled for ½ hour, and an old one for 2-3 hours.

**Cooking Times for Tongues.**—*Sheep's* tongues, 1½-2 hours; *calves'* tongues, 1½-2 hours; *ox* tongue, 4½-6 hours; *ox* tongue (pickled), 2½-3 hours.

## Boiled Fish

This method is suitable for large whole fish, or thick cuts of white fish or salmon. Small fish are better steamed.

To prepare a whole fish, wash quickly in cold water, remove the guts, scales, fins, and eyes, and rub off any black skin from the inside of the fish, using a little salt. Thick cuts of fish only need wiping or scaling. Have sufficient water in the pan to cover the fish, and add a teaspoonful of salt to each quart of water, or for white fish a teaspoonful of vinegar. Draw the pan off the heat, place the fish in the water, and cook very gently for the required time. As fish is very tender and breaks easily, it is best to cook it at just under simmering point.

**Times for Cooking.**—For a large fish allow 10

minutes to the pound and 10 minutes over. Cook small fish until the flesh is firm and will leave the bone quite clean (10-15 minutes).

## Vegetables

Boiling is a very satisfactory way of cooking vegetables, as it softens the cellulose, but in order to retain the maximum amount of nutriment the "conservative" method should be followed. Allow sufficient water to just cover the vegetables—for green vegetables approximately ½ pint water to 1 lb. greens. Add salt in the proportion of 1 teaspoonful to 1 pint water. Bring the water to the boil, and retaining boiling point throughout, add the vegetables a handful at a time. The outside leaves of green vegetables should be added first, followed by the medium green ones, and lastly the heart. Place a well-fitting lid on the pan to prevent steam escaping, and shake two or three times during cooking.

**Times for Cooking.**—*Green Vegetables.*—Shredded, 7-10 minutes; brussels sprouts, 10-15 minutes; spinach, 15-20 minutes; peas, 10-15 minutes; beans, 20-30 minutes; beans (runner), 15-20 minutes.

*Root Vegetables.*—Diced, 20-25 minutes; sliced, 30-35 minutes; quartered, 30 minutes or more, according to age.

## Puddings

With the exception of suet puddings, it is more satisfactory to steam, rather than boil, puddings. Boiled puddings tend to become waterlogged. A suet pudding should be wrapped in a scalded cloth which has been well floured on the inside. Place the pudding in rapidly boiling water, and keep boiling gently for the required time.

**Time to Allow.**—A meat or fruit pudding for 4 people, i.e., ½ lb. flour will take about 2 hours.

## Cereals and Pulses

Oatmeal, rice and macaroni, pulses such as peas, beans, and lentils all boil well.

**Oatmeal Porridge.**—Bring 1 pint water to boiling point, and sprinkle in 2 tablespoonfuls medium oatmeal, stirring well. Continue to stir until boiling point is again reached, and boil for a few minutes, then allow to simmer, in a double saucepan if possible, for ½-2 hours, according to the size of the grains, until the oatmeal is well swollen and tender. More boiling water may be added if necessary, to make the porridge of a good pouring consistency. Salt to taste.

Commercially prepared oats or rolled oats can be cooked very quickly, according to the directions on the packet.

**Rice (To Serve as a Vegetable or Garnish).**—Allow about 2 oz. rice for each person. Wash thoroughly and put into a pan with plenty of boiling salted water. Boil rapidly without a lid for 15-20 minutes, until the grains are tender but not crushed. During boiling the grains of rice should dance about in the water. Drain the rice through a sieve, saving the water for soups, then hold under the running cold tap to rinse the rice thoroughly. Spread the rice on a cloth, turn the edges over and keep in a warm place to heat through and dry off. At intervals fork the rice, so that every grain is dry and separate.

**Macaroni.**—Allow a quart of salted water to 4 oz. macaroni. Place the macaroni in fast-boiling water and boil rapidly, stirring occasionally to prevent sticking, for 20–30 minutes. Some proprietary brands cook quicker—see directions on packet.

**Pulses (Dried Peas, Beans, and Lentils).**—Soak for 12–24 hours in warm water, with a good pinch of bicarbonate of soda. Place the pulses in a pan of fresh salted water, and simmer for 2–3 hours, or until tender; lentils take only 1 hour.

### GRILLING

Grilling is one of the simplest and quickest methods of cooking. The grill should be well heated before use. The heat can be adjusted during the cooking by raising or lowering the grill pan. This can be done either by an adjustment in the pan itself or in the fitting in which it slides. Failing either of these facilities, raise it by placing a suitable tin under the pan.

**Re-heating Foods under the Grill.**—When serving vegetables *au gratin* or similar dishes, heat the vegetables in the sauce in a pan, and then empty into a hot fireproof dish, choosing a shallow one if possible. Sprinkle the top with grated cheese, breadcrumbs, etc., and immediately place under the grill, keeping the surface of the food directly under the heat until evenly brown. The dish should be fairly close to the heat, and it may be necessary to raise your grill pan by putting a tin or plate under it.

**Choice of Meat.**—Only tender and juicy cuts of meat are suitable for grilling, and the piece of meat you choose must be well hung, otherwise it will be tough and stringy when cooked. Fresh, underhung meat will never grill satisfactorily. Rump and fillet steak, chump chops, cutlets, tender liver, and kidneys, all make delicious grills.

**Preparation and Cooking.**—Wipe the meat with a damp cloth, cut steak into portions if necessary, leaving where possible a rim of fat; remove the spinal cord from chops; wash and wipe liver and kidneys, cutting them in half and removing the core. Brush all meat with oil or melted fat before placing on hot grid.

The heat should be intense to begin with, so have the grill red-hot. Place the meat on the greased grid and heat quickly, so that the surface juices coagulate and form a skin, keeping in the flavour and goodness. Allow about two minutes for the "sealing," until the meat has changed colour. As soon as one side of the meat has been sealed, turn and treat the other side in the same way. Do not wait too long, or the surface will become hard and overcooked. Thick chops or steaks require 10–15 minutes, and during this time they should be turned four or five times. Turn the meat with two spoons, taking care not to pierce the flesh, or the juice will run out.

**Choice of Fish.**—Herrings, mullet, mackerel, cod and salmon cutlets, plaice and soles, are all suitable for grilling.

**Preparation.**—Wash whole fish, remove scales, score with a sharp knife in three or four places, and brush with melted fat. Place on the hot greased grid and cook rather slowly, so that the fish is thoroughly cooked without any fear of burning. Turn once or twice, but handle the fish very carefully, as the flesh breaks easily. Insert the back of the knife next to the bone to see when the fish is cooked. Serve with lemon-juice and chopped parsley sprinkled over the fish.

**Cutlets of Fish.**—Tie the cutlets, to keep them a good shape; brush with fat, place on the greased grid and grill on both sides until the fish is cooked—about 10 minutes. Salmon cutlets are grilled in the same way.

**Grilled Bacon or Ham.**—Place the rashers or ham on the grid, place under the grill and cook for two or three minutes, or longer if the rashers are thick. As soon as the fat is transparent on one side, turn and cook on the other side. If eggs are cooked in the grill pan, the grid should be removed and the egg broken carefully into the fat and cooked until set.

**Sausages.**—Prick sausages, arrange on the grid, and place under the grill. Cook rather slowly until well browned all over, turning them frequently.

**Times for Grilling Meat.**—The following table gives approximate times which vary according to thickness of the meat:—

Steak: under-done	10–15 minutes
well done	15–20 minutes
Lamb or mutton chops	10–20 minutes
Pork chops	25 minutes
Veal cutlets	15–20 minutes
Liver	5–10 minutes
Kidneys	10 minutes
Bacon rashers	2–3 minutes
Ham	10–15 minutes
Sausages	10–15 minutes

### FRYING

There are two main methods of frying, shallow frying and deep frying.

#### Shallow Frying

This is suitable for foods like chops, sausages, bacon, fish, pancakes, eggs, cooked potatoes or vegetables, which only require sufficient fat to prevent them from sticking to the frying-pan, or made-up dishes, such as fish cakes or rissoles, which need sufficient fat to half-cover the food.

Heat the fat until just smoking hot in the pan before putting the food in. Cook the food quickly on both sides until the surface is lightly browned. Reduce the heat and finish cooking gently. When cooked lift from the pan, allow fat to drain off, and then place on a crumpled piece of kitchen paper to finish draining; arrange on a hot dish, and serve at once. Any remaining fat should be strained into a bowl for further use. Fat used for frying fish should be kept separately. It is important to avoid over-heating of the pan and fat when shallow frying, or particles of food may become burnt and spoil the flavour of the dish.

#### Special Directions

**Bacon.**—Cut the rinds off the bacon, then put these and the rashers in a cold frying-pan, place over a gentle heat and cook until the bacon fat is transparent and the rashers just begin to curl. Remove from the pan, then, if convenient, use the fat for frying potato cakes, cooked sliced potatoes, or an egg. When frying an egg remember to baste it with the hot bacon fat in order to cook the top surface properly.

**Sausages.**—Heat about a tablespoonful of fat in the pan. Prick the sausages with a fork and put them in the hot fat and fry over very gentle heat, turning them until they are lightly browned on all sides. The secret of cooking sausages is to cook them very slowly—but they must be thoroughly done and nicely browned.

**Fish.—Fillets.**—Wipe and dip in seasoned flour. Have a small quantity of fat smoking hot in the pan and place the fillets in this. Fry until lightly browned, then turn and fry on the other side. Cook gently until the flesh is white and firm. As fish breaks easily, it must be handled carefully.

**Herrings.**—Very little fat is required for frying herrings, as they are a naturally oily fish; in fact, it is quite possible to fry herrings without any fat in a really strong iron frying-pan. Scale, clean, wash, and dry the herrings. Sprinkle the pan with salt and heat gently at first, shaking occasionally. Continue heating until the pan is almost red hot, then lay in the herrings. Fry on each side until golden-brown and crisp—3 to 4 minutes each side. Serve piping hot.

**Chops and Steaks.**—Wipe the meat and place in a little hot fat in the pan. Fry quickly on both sides until lightly browned, then reduce the heat and cook very gently until the meat is tender. (Test with a thin skewer if necessary.) Remember when once the outside surfaces are brown the heat must be reduced, otherwise the meat will be dry on the outside and unpleasantly raw inside. The time for cooking chops and steaks depends on the thickness and texture of the meat, but a thin chop or steak will take about 10–12 minutes.

**Liver.**—Slice the liver across the grain in pieces  $\frac{1}{2}$  in. thick, toss in seasoned flour, and fry as for chops and steaks.

#### Deep Frying

This is suitable for made-up dishes such as croquettes, rissoles, fritters, fish coated with batter or egg and bread-crumbs, whitebait, doughnuts, etc. For this method a deep-fat frying-pan is used with a fitted wire basket, and there must be sufficient fat to allow the food to be completely submerged, *i.e.*, about three-quarters filled. Suitable fats are olive oil, lard,

block suet, or clarified dripping. All food cooked in deep fat, with the exception of potatoes and pastry, must be coated with egg and bread-crumbs or batter; flour is not a suitable coating for deep-fat frying. Heat the fat until a faint blue smoke rises from it. Any excess bubbling or spitting is due to moisture in the fat, and the pan must be heated very gently until this ceases. The prepared food should be placed in the basket, and the pan of fat drawn to the side of the heat. Lower the basket into the fat and replace over the flame or hot-plate. If the food is added while the fat is over the heat it may bubble over and catch on fire. Cook the food until it is golden-brown, lift the basket and drain off surplus fat. Turn the food on to crumpled kitchen paper to finish draining, and finally arrange in a dish and serve very hot. When large quantities of food are to be cooked, fry a little at a time to avoid lowering the temperature of the fat.

Should the fat accidentally catch on fire, turn off the current or burner immediately, and place a lid quickly over the pan of fat.

The used fat can be strained into a container for further use.

The temperature for deep-fat frying is very important. If it is not hot enough the food becomes sodden with grease, and if too hot the outside will be burnt. Average temperatures vary between 395° and 350° F., according to different foods.

If a thermometer is not available the temperature may be tested as follows: put one or two 1-in. cubes of bread into the hot fat; if they take 60 seconds to brown, the fat is about 350–365° F.; if they take 40 seconds, it is about 365–382° F.; if they take only 20 seconds, the fat is about 382–390° F.

### Special Directions

**Egging and Crumbing.**—This is suitable for fillets of fish, cutlets, rissoles, fish cakes, and croquettes. First coat the food lightly with seasoned flour. Have some beaten egg on a plate, and taking one piece of food at a time, brush it all over with the beaten egg, using a pastry brush. Have ready some fine bread-crumbs on a piece of kitchen paper. Lift the coated food on to the crumbs, carefully draining off any excess egg. Holding the sides of the paper, toss the crumbs so that they cover the food. Pass from one hand to the other to remove any loose crumbs, then place in the frying-basket.

**Coating Batter.**—Batter is a suitable coating for fritters (fruit or vegetable), fillets of fish, kromeskis, etc. Any good batter recipe can be used—it should be mixed to the consistency of thick cream. Place the food to be cooked, a piece at a time, in the batter, allow any excess batter to drip off, and place immediately in the smoking fat. When golden brown and cooked through, drain carefully and dish.

**Chipped Potatoes.**—Special care must be taken when frying potatoes in deep fat. They must be thoroughly dried, otherwise when they are placed in the fat will splutter and an accident may be caused.

First peel the potatoes and cut them into chips, straws, or scallops. If they have to be prepared in advance leave in cold water. Just before frying drain off the water, spread them out on a clean dry cloth, rub them carefully with the cloth so that all surfaces are dry, then place in the frying-basket. When lowering the basket into the fat take great care that the fat does not froth over.

Chipped potatoes take about 20 minutes to cook. To ensure they are not sodden cook them until tender, but not crisp, then lift out the basket and reheat the fat. When at smoking point, replace the basket in the fat and cook until brown and crisp. Drain carefully, and sprinkle with salt before serving.

### To Render Down Fat

Any pieces of meat fat can be used to prepare frying-fat. Cut the fat into pieces about  $\frac{1}{2}$  in. square, removing any scraps of meat or gristle, put into a pan, cover with water, and allow to boil slowly for several hours until the water is driven off and the pieces of fat are fried and shrivelled. Strain off the fat.

Another method is to place the cut-up fat in a tin and cook it in a slow oven to extract the fat.

This method is easier but is more wasteful of fat, as much of it is left in the particles of skin when drained.

### ROASTING

This is one of the most popular ways of cooking meat, poultry, and game. There are two different methods of roasting: one for good-quality and tender joints, the other for poorer-quality meats. In either case the preparation of the meat is the same.

Wipe and weigh the meat, tie in shape if necessary, and stand on a trivet in a shallow roasting-tin. Always place the meat fat side up to allow it to melt, and baste the meat as it does so. A tablespoonful or so of fat should be placed on the meat, and a piece of fat bacon on lean meats, such as game or veal. Basting is not necessary. Small joints such as breast or loin of lamb or veal can be boned and stuffed. Prepared vegetables should be placed round the joint. When the joint is cooked, it should be taken out of the oven and the gravy made in the tin. Remove the meat and vegetables from the fat, and place on a dish to keep warm. Pour off the dripping, leaving the sediment in the bottom. Add to it sufficient fat to soak up the fat—about 2 teaspoonfuls to every 1 pint of gravy needed—mix with the sediment and then place over the heat and stir until the flour is a golden brown. Pour on liquid, which should be stock or vegetable water. Bring to the boil and season. It may be necessary to add a few drops of gravy browning. Gravy should be of a thin pouring consistency, and free from grease.

If a covered roasting-tin is used the top should be removed 30 minutes before the meat is done, in order to brown the outside.

### Times and Temperatures for Roasting Meat

**Method 1.**—Place the joint in an oven heated to 425° F. Reduce the temperature to 400° F., and allow the following times for cooking: beef, 15 minutes to the lb. and 15 minutes over; beef, thick cut or rolled, 30 minutes to the lb.; mutton, 25–30 minutes to the lb.; mutton, stuffed, 30–35 minutes to the lb.; veal and pork, 30–40 minutes to the lb.

**Method 2.**—Put joint into a cold oven, raise the temperature to 300–350° F. and allow: beef, 25–35 minutes to the lb.; beef, thick cut or rolled, 30–40 minutes to the lb.; mutton, 30–40 minutes to the lb.; mutton, stuffed, 35–45 minutes to the lb.; veal and pork, 40–50 minutes to the lb.

Bird	Time
Chicken . . .	1 hour
Duck . . .	1–1½ hours
Goose . . .	1½ hours or longer
Guinea Fowl .	30–45 minutes
Pigeon . . .	20–30 minutes
Turkey . . .	15 minutes per lb. (weight after dressing) for birds up to 14 lb.; 10 minutes per lb. for larger birds
Pheasant . . .	30–60 minutes according to size
Grouse . . .	½–¾ hour
Partridge . .	25 minutes

### POT ROASTING

This is a particularly suitable method for tough joints, and is also an alternative to roasting when no oven is available.

Rub the meat over with seasoned flour. Melt some dripping, allowing about 1 tablespoonful to each lb. of meat, in a saucepan with a well fitting lid. Brown the meat on all sides, and add about a  $\frac{1}{2}$  pint of water. Slip a trivet under the meat, cover tightly, and leave to cook gently until tender, turning the joint from time to time. The average joint takes 1½–2 hours. Vegetables such as diced carrot, turnip, or onion can be added to the pot an hour before serving. Herbs can be used for flavouring.

### STEAMING

One of the most economical methods of cooking food, and one which has the advantage of retaining mineral salts which otherwise may be dissolved out when food is boiled in water. The chief points to remember are that the steamer must never be allowed to boil dry and the water must not be allowed to go off the boil.

## Methods of Steaming

1. *In a Steamer with Perforated Base Placed over an Ordinary Saucepan.* The steamer must fit the saucepan well. Soups or a vegetable can be cooked in the bottom of the steamer, a pudding with some vegetables round it can go in the top, and if required fish can be steamed on a plate on top of the steamer.

2. *In a Tiered Steamer.* This is an extremely useful utensil, but care must be taken to see that the steam enters all compartments, and the regulator knobs should be checked each time it is used. Different dishes can be cooked in each tier without any fear of flavours becoming mixed.

3. *In Jam-jars, Basins, or Moulds in a Pan of Boiling Water.* The water should reach half-way up the jar or basin. For a delicate dish, such as a soufflé, the mould or tin should be placed on an upturned saucer, pastry cutter, or tin. The water in the pan may be replaced by soup, or vegetables can be cooked in the water and different foods in each jam-jar.

4. *In a Compartment Steamer—Saucepan.* These pans are sold with several compartments fitted into the saucepan, and are useful for small families. The method is the same as when using pudding-basins.

5. *In a Double Saucepan.* This is a suitable way of cooking sauces, stews, porridge, etc. They take longer, but there is no fear of their boiling or burning, and sauces do not need constant stirring.

**Meat.**—Any joint of meat can be steamed. Allow twice as long as for boiling. Soak salted meat for 3 hours beforehand.

**Poultry.**—The time depends very much on the size and age of the bird. A good way of cooking an old fowl is to steam it until it is tender, then to brown it in a hot oven (450° F.) for ½ hour.

**Fish.**—Prepare the fish as for boiling. Place large cuts or whole fish directly in the steamer. Small fillets or thin cutlets will cook satisfactorily if laid on a greased plate with a tablespoonful of milk and seasoning. Cover with a lid, then lay the plate on top of the steamer or pan.

## Time for Steaming

**Fish.**—For a large fish allow 15 minutes to each lb. and 15 minutes over. Cook fillets until the flesh is firm—about 20 minutes.

**Vegetables.**—Steaming is only suitable for root vegetables, as in green vegetables the loss of vitamins and mineral salts is too high, and flavour and colour are likely to be impaired. Potatoes can be scrubbed and steamed in their jackets. Other root vegetables should be peeled. Sprinkle the prepared vegetables liberally with salt. Allow half as much time again as for boiling.

**Puddings.**—To keep out the moisture caused by condensation, the pudding should be covered with greased paper or a cloth dipped in hot water and floured. A basin-cover or string should be tied round the basin, so that it may be easily lifted out of the steamer.

Suet puddings need 3 hours or longer. Sponge puddings in small dariole moulds cook in 20 minutes; larger puddings take ½–2 hours, according to the size. Allow plenty of room in the basin for the pudding to rise.

**Custards.**—The water should be only just boiling for these, as they curdle if the temperature becomes too high. Remove as soon as they are set (about ½ hour.)

## STEWING

A long, slow method of cooking in a liquid kept just below simmering point. A good strong pan with tightly fitting lid should be used, or alternatively a casserole, steamer, or double boiler. Stewing can be done either in the oven or over a low heat. It is important not to raise the temperature above boiling point, or the food becomes tough or broken up.

## Stewed Fruit

**Preparation.**—Peel, core, or stone and, if necessary, cut up into neat pieces.

**Cooking.**—To keep individual pieces of fruit whole and of good shape (e.g., to serve as stewed fruit, for fruit in jelly, fruit trifle, and so on) stew them gently in a syrup made from sugar and water. The proportions will vary with the juiciness and sweetness of the fruit, but ½–1 pint water and 2–4

oz. sugar to 1 lb. fruit is the average. Lift out the fruit, simmer the juice until it is slightly syrupy, and pour over the fruit.

If the fruit is required stewed to a mash to make into a purée (for fruit fools, creams, and so on), it is better to cook it without sugar and in the minimum of water until tender, and then to sweeten it, since the addition of sugar to the raw fruit toughens the skin and may prevent it mashing properly.

Some fruits are improved by the addition of other flavouring. Apples may be flavoured with lemon juice, grated lemon rind, cloves, cinnamon stick, or marmalade (remove cloves or cinnamon before serving), pears with cloves or cinnamon stick. Plums may be flavoured with their kernels or a few sweet almonds, rhubarb with root ginger, cinnamon stick or strip of lemon rind; remove before serving.

## Stewed Dried Fruit

Wash ½ lb. fruit, such as prunes, very thoroughly, add ½ pint water, and allow to soak for at least 12 hours. Put the fruit in a saucepan with the water and 1–4 tablespoonfuls sugar, according to fruit, and bring to the boil, simmer gently until tender. Remove the fruit, boil the juice for a few minutes, until syrupy, then pour it over the fruit. Alternatively, the fruit may be steamed until tender—it will take at least half as long again as stewed fruit.

## Meat Stews

**Brown.**—For this type the meat, vegetables, and flour are fried before stewing. Stewing steak is commonly used for brown stews, but other meats such as oxtail, kidney, and liver may be used.

**White.**—Mutton, veal, or rabbit is generally used for white stews, and the meat and vegetables are not fried first. Irish stew is an example of a thin white stew, while a fricassee is a thickened white stew.

The cheaper and coarser the meat, the longer it takes to cook. Most types of stew require at least 2 hours, and some varieties, such as oxtail and brisket, may take 3 or even 4 hours. Herbs, spices, and vegetables should be added in moderation to give flavour and interest to the stew.

For recipes see following chapter.

## PRESSURE COOKERY

By cooking foods in specially designed pressure cookers it is possible to cook at temperatures above the normal boiling point of 212° F. This is a particularly valuable method of cooking foods which normally require long, slow cooking, such as stews, soups, root vegetables, tough joints of meat, etc. Considerable time and fuel can be saved.

There are many varieties of pressure cooker now on the market, in each case the manufacturers' instructions should be carefully followed, and the directions for sealing the cooker and controlling the pressure thoroughly understood.

With most cookers the prepared food is placed in the pan with the required quantity of liquid. The lid is fixed into position and the pan is placed over a high heat, and the contents brought to pressure point. The heat is then reduced, and the cooking time is calculated from that point.

The following points should be remembered:

1. The cooker should never be filled too full—not more than two-thirds full for solid foods and half-full for liquids, cereals, and preserves.

2. The times given in the charts should be followed, but there will probably be slight variations due to the thickness and quality of the food, especially meat and poultry, etc.

3. Always allow pressure to drop to normal before attempting to open the pan; either reduce pressure immediately by running cold water over the side, or in the case of milk puddings, cereals, dried vegetables, and stewed fruit, allow the cooker to cool slowly for 5–10 minutes at room temperature.

4. After use the cooker should be carefully washed. Store with the lid off so that the air can circulate.

Times for pressure cooking cannot be guessed. The following tables will serve as a guide, though fuller instructions should be followed from the manufacturers' or other special recipe book.

## PRESSURE-COOKING TIME-TABLE FOR MEAT OR BIRD

Meat or bird.	Water.	Cooking time (at 15 lb. pressure).
Beef—Boil . . . . .	1 pt.	9-10 minutes per lb. plus 10 minutes
Roast—pre-fry . . . . .	$\frac{1}{2}$ pt.	
Mutton, Lamb, and Veal—Boil . . . . .	1 pt.	10-12 minutes per lb. plus 10-12 minutes
Roast—pre-fry . . . . .	$\frac{1}{2}$ pt.	
Pork—Boil . . . . .	1 pt.	12 minutes per lb. plus 12 minutes
Roast—pre-fry . . . . .	$\frac{1}{2}$ pt.	
Chops (Veal, Pork, Mutton, and Lamb)—pre-fry . . . . .	$\frac{1}{2}$ pt.	5-6 minutes according to thickness
Young Chicken, Duck, Guinea Fowl, Pheasant, and Grouse . . . . .	"	6-8 minutes
Partridge and small birds such as Snipe and Woodcock . . . . .	"	15 minutes in all
Old Fowl (approx. 3 lb.) . . . . .	1 pt.	30-35 minutes, according to age

## PRESSURE-COOKING TIME-TABLE FOR STEAMED FISH

Fish.	Water.	Cooking time (after 15 lb. pressure is reached).
Bream, Halibut, Fresh Haddock, Hake, Skate, Turbot . . . . .	$\frac{1}{2}$ pt. water or to level of rack, but extra water when fish is in greaseproof paper	3-4 minutes for cutlets; 4-5 minutes per lb. for whole fish
Cod . . . . .	" " "	3-4 minutes for cod steaks; 4 minutes per lb. for whole fish
Haddock (dried)	$\frac{1}{2}$ pt. milk and water	3-5 minutes, according to size
Herrings, Trout, Mackerel . . . . .	$\frac{1}{2}$ pt. water	Melt a small knob of fat at bottom of cooker, dip fish in seasoned flour and cook rapidly on both sides in hot fat. Lift on to rack and add $\frac{1}{2}$ pt. water, and continue cooking as above, allowing 4-6 minutes according to size
Plaice or Sole . . . . .	$\frac{1}{2}$ pt. water or to level of rack, but extra water when fish is in greaseproof paper	Whole fish, 2-4 minutes per lb. according to size. Fillets, 2-3 minutes
Salmon Steaks . . . . .	" " "	6-7 minutes, according to thickness. Be sure to wrap fish in well-greased paper
Scallops . . . . .	" " "	4-5 minutes

## PRESSURE-COOKING TIME-TABLE FOR VEGETABLES

Vegetables.	Water.	Cooking time (at 15 lb. pressure).
Artichokes (Jerusalem) . . . . .	$\frac{1}{2}$ pt. or to level of rack	8-10 minutes
(Globe) . . . . .	" "	10 minutes
Asparagus . . . . .	" "	2-3 minutes
Beans (Broad) . . . . .	" "	3-4 minutes
(French) . . . . .	" "	3 minutes
(Runner) . . . . .	" "	2-3 minutes
Beetroot . . . . .	" "	10-35 minutes, according to size and age
Brussels Sprouts . . . . .	" "	3-4 minutes
Cabbage, Spring Greens . . . . .	" "	2 minutes
Carrots (diced) . . . . .	" "	2-3 minutes
(whole, young) . . . . .	" "	3-5 minutes
(large) . . . . .	" "	8 minutes
Cauliflower (sprigs) . . . . .	" "	2 minutes
(whole) . . . . .	" "	5-6 minutes
Celery . . . . .	" "	2-3 minutes
Corn on the Cob . . . . .	" "	4 minutes
Leeks . . . . .	" "	3-5 minutes
Onions (whole) . . . . .	" "	10 minutes
(sliced) . . . . .	" "	3-4 minutes
Parsnips . . . . .	" "	As for carrots
Peas . . . . .	" "	1-2 minutes
Potatoes (new) . . . . .	" "	10 minutes
(old) . . . . .	" "	8-10 minutes
Spinach . . . . .	" "	1-2 minutes
Swedes . . . . .	" "	5 minutes
Turnips . . . . .	" "	5 minutes
Vegetable Marrow . . . . .	" "	3-4 minutes

## PRESSURE-COOKING TIME-TABLE FOR CEREALS

Cereal (4 oz.).	Water.	Cooking time (at 15 lb. pressure).
Macaroni . . . . .	1 pt.	5-8 minutes

Raspberries . . . . .	"	Merely bring to pressure
Rhubarb . . . . .	"	2 minutes

## PRESSURE-COOKING TIME-TABLE FOR DRIED VEGETABLES

Vegetable (4 oz.).	Water.	Cooking time (after 15 lb. pressure is reached).
Butter and Haricot Beans (soak 2 hours) . . . . .	$\frac{1}{2}$ pt.	15-20 minutes
Lentils . . . . .	"	20-25 minutes
Peas (soak 2 hours) . . . . .	"	15-20 minutes
Split Peas . . . . .	"	10-15 minutes

PRESSURE-COOKING TIME-TABLE FOR DRIED FRUIT  
Previously soaked for 12 hours

Fruit (1 lb.).	Water.	Cooking time (at 15 lb. pressure).
Apple rings . . . . .	$\frac{1}{2}$ pt.	5-6 minutes
Figs . . . . .	1 pt.	10-15 minutes
Prunes . . . . .	$\frac{1}{2}$ pt.	6-10 minutes
Apricots and Peaches . . . . .	$\frac{1}{2}$ pt.	6-10 minutes

### III. WINES

The finest of the world's wines come from France, Italy, Spain, Portugal, Rumania, Switzerland, the Balkans, and Germany, although much wine is now made in Algeria, Australia, South Africa, North and South America. Wine is the suitably fermented juice of fresh grapes. The flavour of a wine depends not only on the species of grape used, but also on the methods of fermentation and the different salts contained in the soil where the grape is grown. Therefore the quality and flavour of wines vary greatly according to different vineyards. The degree of fermentation also affects the sweetness of the wine; in dry wines all the grape sugar is converted into alcohol, whereas in sweet ones the process is stopped or arrested.

#### TYPES OF WINE

*Beverage wines* are the cheapest wines, and are commonly drunk in the country where they are produced. They are of a good colour and body, but do not improve with keeping. The alcoholic content varies between 8 and 12 per cent of their volume. These wines can be drunk alone or diluted with water. Beverage wines such as Claret and Burgundy travel well, and are widely exported, but those such as Chianti or Vin Rosé tend to travel badly, although they are available in different parts of the world.

*Sound wines* come as the result of fermentation of the grapes only. They are well balanced and distinct from fine wines, which are perfectly balanced.

*Fine wines* are the most expensive wines, and are so perfectly balanced that they will go on improving for many years in the bottle. Most of these wines come from the Côte-d'Or and Gironde regions of France.

*Sparkling wines* are bottled before fermentation is complete, and because of this the corks must be wired to the bottle. These wines keep well. Champagne is the best known example of a sparkling wine.

Among the best-known wines are the following:

Sherry is made in Spain from the best wine of each year's vintage blended with brandy. Dark sherry has a special sweet liqueur wine added to give colour and flavour, while light sherry is "dry" in flavour. Sherry is also imported from South Africa.

Champagne is made from grapes grown within the boundaries of the ancient province of Champagne. It is a sparkling wine and is the traditional wine served at weddings. Vintage Champagne is a champagne bearing the date of the year in which the grapes making it were gathered.

Hock is the name given to white wines from the Rhine Palatinate and other parts of Germany. The alcoholic content is about 11 per cent. There are sparkling varieties of Hock.

Moselle is very similar to Hock and of very fine flavour. The sparkling Moselles are the best.

Sauternes is the sweet white wine from Gironde. The average alcoholic content is about 10 per cent. One of the best known of the Sauternes is Chateau Yquem.

Burgundy is a fine, dark-red wine from the French province of Burgundy. There are also white Burgundies, the best known being Musigny, Montrachet, Corton, and Chablis. All Burgundies have a high alcoholic content, but as a rule deteriorate after ten to twelve years.

Claret is the ruby wine from the Bordeaux district of France. The flavour of claret varies a great deal from vineyard to vineyard, and the alcoholic strength is from 8 to 12 per cent.

Port is the rich heavy red wine made originally in the Oporto district of Portugal. It is traditionally served as an after-dinner drink. Legally port wine must be fortified with brandy, and must come from the upper Douro valley, and subsequently be exported through the port of Oporto.

Brandy is a spirit distilled from wine which darkens in the casks as it matures. The quality depends on the type of wine used, the manner of distillation, method and time of storage. Cognac and Armagnac are among the best known and finest brandies.

#### CHOICE OF WINE

The choice of wine for a meal will depend very much on personal taste, but the following rules will serve as a general guide:—

For an apéritif—Sherry, Dubonnet, Chilled Champagne.

With hors d'œuvre—White Moselle, Chablis, Alsace, or Graves.

With Soup—Sherry or Madeira.

With fish, poultry, or white meat—White Hock, Burgundy or Champagne.

With red meat and game—Red wine—Claret, Burgundy, Beaujolais, etc.

With Sweets—Sauternes, Champagne, Anjou, or Palatinate Hock.

With (or after) Coffee—Port, Brandy, Liqueurs.

The preparation and service of wine is important. Bottles must always be carried carefully to avoid disturbing the sediment. White wines are chilled to 50° F. by standing them on ice or in a cold place. Red wines should be brought gradually to the room temperature of about 60° F. Light wines should not be decanted, but it is permissible to do so with red wines, particularly if the whole bottle is not to be drunk at one sitting.

#### WINE-GLASSES.

Wine should always be served in carefully chosen glasses if the full bouquet is to be appreciated. Serve it in colourless glasses so that colour of the wine itself can be enjoyed. Thick glasses should be avoided and also very small ones, because there must be a fair volume of wine for the bouquet to show off. See that the glasses are well washed and polished with a clean cloth before using them, and do not fill them too full. Many differently shaped glasses of various sizes are made for serving wines. These have all been designed for special reasons, and the most usual ones are given in the list below:—

Sherry.—A fairly small long-sided glass.

Burgundy, Claret and White Wines.—A large bowl-shaped glass. Claret is sometimes served in a tulip-shaped glass so that it can be held in the hand and its contents maintained at body temperature.

Hock and Moselle.—A long-stemmed glass with a fairly small cup-shaped bowl. The length of the stem keeps the hand away from the wine, and so avoids spoiling the temperature.

Champagne and Sparkling Wines.—A large saucer-shaped glass. The expanse of surface allows the bubbles to dance on the wine. Some people prefer a tulip-shaped glass so that a steadily rising stream of bubbles can be maintained.

Port.—A glass similar to that used for sherry, but slightly larger.

Brandy and Liqueur glasses are included in most sets of wine-glasses. Liqueur glasses are small with a narrow opening. These can be used for brandy, although old Liqueur brandy is often served in large goblets known as brandy balloons.

#### STORAGE AND BUYING OF WINES

Wine should be stored in suitable racks, with the bottles lying on their sides, in order to keep the corks damp. They should be in a cool, dark cellar or cupboard. Leave the bottles undisturbed, as movement does not improve the wine.

It is best to buy from a reliable merchant, as even the best wines can be ruined by bad storage, bad bottling, or too much shaking in transit. Vintage wine bears a date on the label, and it is expected to mature well, being the product of a year when climatic conditions were good. The date, however, serves only as a guide to the buyer, as there are good and bad wines in vintage and non-vintage years. The following are good vintage years.

Ports	1027, 1935, 1941
Clarets	1929, 1934, 1937, 1943, 1945, 1947
Burgundies	1929, 1933, 1943, 1945, 1947
Champagnes	1934, 1937, 1943, 1945
Hocks	1934, 1937, 1942, 1945

## IV. DIRECTIONS AND RECIPES FOR TYPICAL DISHES

## SOUPS

The basis of all good soup is stock, and it should be used when available. Stock can be made from any scraps of meat, bones—cooked or uncooked—and root vegetables. Fish stock must be made separately and used only for fish soup.

**Bone Stock.**—Use a large pan with well-fitting lid and place the bones in it with pieces of root vegetable, and a *bouquet garni* (bunch of herbs). Cover with cold water, season, and simmer for 2-3 hours. If there is any fat with the bones strain off the liquid, allow to cool, and skim off the fat. Stock should be boiled up every day with additional bones and vegetables. The pot must be emptied and cleaned about every third day.

**Vegetable Stock.**—Cut up a variety of vegetables, being careful to avoid including too much of a strong-flavoured variety such as turnip. Cover with cold water and flavour with seasoning, a bay leaf, clove, a blade of mace, and herbs. Simmer until a good flavour is obtained. Use fresh.

**Fish Stock.**—Put fish bones and skin with herbs, spice, and seasoning into a pan. Cover with water and simmer for 1 hour. Use same day.

Soups can be divided into the following groups: purées, thickened soups, clear soups, or consommés, broths, and fish soups.

**Purées** are made from puréed vegetables and seldom require additional thickening.

**Thickened Soups** are made from vegetables and other ingredients simmered in stock. They are usually sieved and then thickened according to their ingredients.

**Clear Soups or Consommés** consist of good stock carefully cleared, and entirely free from fat, and served with a garnish which has been cooked separately. Sherry can be added if desired.

**Broths** are made of stock, diced meat, and vegetables. They are thickened with barley or rice, and are never sieved.

**Fish Soups** are made from a foundation of fish stock.

## Consommé

½ lb. lean beef	12 peppercorns
1 small carrot	2 cloves
1 small onion	A blade of mace
A piece of turnip	The whites and shells of
A small stalk of celery	2 eggs
2 quarts best-quality	Salt, if necessary
(or first) stock	A little sherry
A bouquet garni	

Shred the meat very finely, put it into a bowl with enough cold water just to cover, and allow it to soak for about ½ hour. Prepare the vegetables and cut each into four. Put the stock, from which all trace of fat has been removed, into a deep, lined saucepan, add the meat and the water in which it has soaked, the vegetables, herbs, and spices. Lastly, add the whites and crushed shells of the eggs. Put over gentle heat, whisk continuously and bring almost to boiling point; a thick froth should form on the top of the liquid. Stop whisking and continue heating until the froth rises in the pan, then reduce the heat and allow the soup to simmer for a few minutes. Tie a clean white cloth to a jelly stand or to the four legs of an upturned chair and scald with boiling water, then gently pour in the soup. When the consommé has dripped through, strain it a second time—passing it through the frothy egg-whites, etc., to make it clear and sparkling. If necessary, the consommé may be strained a third time.

Reheat the consommé, add salt if necessary, and a little sherry to improve the flavour, but add nothing that would make it cloudy.

## Tomato Soup

1 lb. tomatoes	2 oz. margarine
1 pint vegetable water	Seasoning
2 onions stuck with	2 teaspoonfuls sugar
cloves	1 pint hot milk or milk
4 oz. breadcrumbs	and water

Cut up the tomatoes and put them into a saucepan with all the other ingredients, except the milk. Bring to the boil and simmer with a lid on for 20 minutes, then strain and rub through a sieve. Return to the pan and reheat, then add the milk. Serve with croûtons of toast.

## Potato Soup

6 potatoes	½ pint milk
2 small onions	A small bunch of water-
1 ½ pints water or stock	cress
1 tablespoonful flour	Seasoning

Cook the potatoes and onions in the water until tender. Strain, then press through a sieve. Return to the saucepan, add the flour, blended with the liquid, and bring to the boil, stirring continuously. Wash and chop the cress, and add this to the soup, together with the seasoning. Boil for 3 minutes and serve.

## Lentil Soup

½ pint lentils	A pinch of herbs
1 ½ pints water	½ oz. flour
1 onion	½ pint milk
1 carrot	Salt and pepper
½ oz. dripping	Chopped parsley
A clove of garlic	

Wash the lentils, and if possible soak overnight in the water. Fry the onion and carrot in the dripping, add the lentils and water in which they were soaked, the crushed garlic, and the herbs. Bring to the boil, simmer gently until soft, and pass through a sieve. Blend the flour and milk, add to the purée and season, bring to the boil, and boil for a few minutes to cook the flour. Sprinkle in the chopped parsley and serve.

## Artichoke Soup

1 ½ lb. Jerusalem arti-	2 pints stock or water
chokes	Salt and pepper
1 stalk of celery	1 oz. flour
2-3 bacon rinds	½ pint milk
A little fat if required	Chopped parsley

Peel and slice the artichokes, chop the celery and sauté them in the fat from the bacon rinds, adding a little more fat if necessary. Add the liquid and seasoning, bring to the boil, and simmer until the vegetables are tender. Pass through a sieve and return to the saucepan. Add the flour, blended to a smooth cream with the milk, bring to the boil, and cook for 2-3 minutes, re-seasoning if necessary. Add the parsley.

## Green Pea Soup

2 lb. peas	1 oz. flour or ½ oz. corn-
1 quart stock or water	flour
A sprig of mint	½ pint milk
Seasoning	

Shell the peas and wash the pods in several waters. Place the pods in a pan, cover with the stock or water, and allow to simmer gently for about ½ hour, to extract flavour and colour. Strain off the stock, return to the pan with the peas, mint, and seasoning, and simmer until the peas are tender. Pass through a sieve. Blend the flour or cornflour with the milk, add to the soup, re-boil, stirring all the time, and serve.

## Celery Cream Soup

Outside stalks of 1	Salt and pepper
large head of celery	A bouquet garni
1 medium-sized onion	1 oz. flour
½-1 oz. fat	½ pint milk
2 pints stock or water	Chopped parsley

Prepare and slice the celery and onion, and sauté in the fat for about 10 minutes. Add the stock or water, seasoning, and bouquet garni, bring to the boil and simmer until the vegetables are quite tender. Pass the soup through a sieve and return to the saucepan. Stir in the flour, blended to a smooth cream with the milk and allow to boil for a further 2-3 minutes. Re-season if necessary, and add the freshly chopped parsley just before serving.

## Pot au Feu

2 lb. lean beef	2 small leeks
2 ½ quarts water	2 stalks celery
Salt	A bouquet garni (in-
1 carrot	cluding a small blade
1 turnip	of mace, 12 pepper-
1 onion	corns, and 2 cloves)
1 parsnip	1 oz. seed pearl tapioca
1 small cabbage	or semolina

Tie the meat into a neat shape, put into a large saucepan, add the water and 1 teaspoonful salt

and simmer for 2 hours. Prepare the vegetables, cut each into quarters, with the exception of the cabbage, and add to the broth with the bouquet garni. Continue to cook for another 2 hours. Cut the cabbage in two, but tie together so that it does not break whilst boiling, put into the pot and boil until tender. Serve the meat on a dish with some of the liquor; garnish with the vegetables. If liked, the cabbage may be dished separately.

To make soup from the liquor sprinkle in the seed pearl tapioca or semolina, cook for 15 minutes and serve.

The meat and broth may be served separately or together, whichever is preferred.

### Simple Minestrone

- |                         |                                   |
|-------------------------|-----------------------------------|
| 1 lb. carrots           | A bouquet garni                   |
| A small piece of turnip | 2 tablespoonfuls macaroni         |
| 2 stalks of celery      | A little ketchup                  |
| 1 lb. artichokes        | 2 tablespoonfuls chopped parsley  |
| 1-2 onions or leeks     | Grated cheese to serve separately |
| 1 oz. fat               |                                   |
| 2 pints stock           |                                   |
| Seasoning               |                                   |

Prepare the vegetables and cut into small, neat pieces. Melt the fat, and sauté the vegetables in it for 5-10 minutes. Add the stock, seasoning, and bouquet garni. Cover and simmer for about 1 hour, then add the macaroni and continue cooking for a further 1 hour, or until the vegetables are quite tender. Re-season and add a little ketchup to taste. Just before serving remove the bouquet garni and add the finely chopped parsley. Serve with grated cheese handed separately.

### Scotch Broth

- |                           |  |
|---------------------------|--|
| 1-1½ lb. lean beef,       | 1 turnip                                 |
| either runner or top-side | 1 medium-sized onion                     |
| 2 quarts water            | 2 leeks                                  |
| Salt and pepper           | 1½ oz. pearl barley                      |
| 1 carrot                  | 1 dessertspoonful finely chopped parsley |

Put the meat into a pan, add the water and salt, bring to boiling point slowly, then simmer gently for 1½ hours. Add the vegetables, previously cut into dice, and the barley. If you do not want the broth to be cloudy it is advisable to blanch the barley before adding it to the stock; to do this, put the grain into cold water and bring it to boiling point, strain, and add to the soup. After adding the barley and vegetables continue to simmer until both are cooked—this will take approximately 1 hour. Serve the meat separately on a dish with a little of the broth. Put the chopped parsley into the soup tureen and pour in the broth. (If the parsley is cooked it loses its green colour.) Should any fat appear on the surface of the broth it must be removed with a spoon or by gently passing a piece of clean unglazed kitchen paper over the top.

### Chicken Broth

- |                     |                        |
|---------------------|------------------------|
| 1 chicken           | 1 dessertspoonful seed |
| Cold water to cover | pearl tapioca          |
| (approx. 2 quarts)  | 1 heaped teaspoonful   |
| Salt                | chopped parsley        |
| 1 onion             |                        |

If using a whole chicken, cut in half, after usual preparation, wash thoroughly, and remove any fat or grease, but retain the skin. Put into a pan and add the water and salt to taste. Peel the onion, cut in half, and add to the contents of the saucepan. Simmer slowly for 3½-4 hours, and if the water boils away, add more. Strain, stand aside until cold, and remove any grease that may have settled on the top of the stock. If time will not permit waiting for the stock to get cold, the grease may be removed by passing a sheet of kitchen paper over the top of the broth. Return the stock to the saucepan, bring to the boil, add the seed pearl tapioca, previously blended with a little of the cold broth, and cook for 10 minutes. Put the chopped parsley in the bottom of a soup tureen and pour the broth over it.

This is an excellent method of utilising an old chicken; if a young one is used, the breast and wings can be removed beforehand and used for grilling or frying.

### Oxtail Soup

- |                          |                             |
|--------------------------|-----------------------------|
| 1 oxtail                 | 1 bay leaf                  |
| 2 onions                 | 2 cloves                    |
| 1 carrot                 | 6 peppercorns               |
| 2 stalks of celery       | Salt and pepper             |
| 1 oz. butter or dripping | 1 oz. flour                 |
| 3-4 pints stock          | A little port wine if liked |
| 1 oz. lean ham or bacon  | Squeeze of lemon juice      |
| A bouquet garni          | or a little ketchup         |

Wash the oxtail, then joint it, and dry the joints. Prepare and cut up the vegetables. Melt the fat in a saucepan, and sauté the jointed oxtail and the prepared vegetables in it for a few minutes. Well cover with stock and bring to the boil. Add the ham or bacon, the herbs, and seasoning, then cover and simmer gently for about 4 hours, or until the tail meat is tender, skimming occasionally. Strain the soup, remove the meat from the tail joints, cut it up neatly and replace it in the strained liquor. Return to the saucepan, stir in the flour, blended to a smooth cream with a little water or port wine. Bring to the boil, stirring, and cook for about 5 minutes. Add more seasoning, if necessary, and a squeeze of lemon juice or ketchup to taste.

### Court Bouillon

To each quart of water (or water and white wine mixed) allow:—

- |                    |                             |
|--------------------|-----------------------------|
| 1 onion            | A small clove               |
| 1 clove of garlic  | 1 tablespoonful vinegar     |
| 1 carrot           | 1 teaspoonful salt          |
| Small stalk celery | Freshly ground black pepper |
| A bunch of herbs   |                             |

Put ingredients into a pan, cover, simmer for 1 hour or longer, strain, and use for cooking fish.

### Fish Cream Soup

- |                   |                                 |
|-------------------|---------------------------------|
| 1 cod's head      | A bouquet garni                 |
| 1½ pints water    | Salt and pepper                 |
| A small carrot    | 1 pint white sauce              |
| 1½ of a turnip    | 1 tablespoonful chopped parsley |
| 1 onion           |                                 |
| 1 stalk of celery |                                 |

Thoroughly wash the cod's head, place in a saucepan, and add the water; bring slowly to the boil and skim well. Prepare and chop the vegetables and add with the bouquet garni to the cod's head and water. Add salt and simmer for about 1 hour. Strain, remove any flesh from the head, and cut into neat pieces. Make the white sauce or re-heat it and blend with the fish stock. Season well and add the fish and chopped parsley just before serving.

### Soup Garnishes

**Bacon.**—Cut into small strips or dice and fry lightly.

**Cheese.**—Grate the cheese (preferably Parmesan or dry Gruyère), and if desired mix it with either chopped parsley or watercress; hand it separately or sprinkle it on the soup just before serving.

**Cheese or Herb Dumplings.**—Mix together bread-crumbs and grated cheese in equal proportions. Season with salt, pepper, mustard, and mixed herbs, and bind with beaten egg, adding a few drops of piquant sauce if desired. Form into small balls and poach in the soup 15-20 minutes before serving.

**Fried or Roasted Croutons.**—Cut bread into slices ½ in. thick, and then into triangles or fancy shapes; bake until golden-brown and crisp, or fry in smoking hot fat, drain, and serve hot. Alternatively, the slices of bread may be toasted first and then cut up.

**Leek.**—Chop and fry.

**Macaroni, Spaghetti, Noodles, Shells, etc.**—Break into short lengths if necessary, and add to the soup about 1 hour before serving.

**Mushrooms.**—Cut into thin slices and fry.

**Onions.**—Slice into rings or chop finely and fry. **Rice.**—Add dry-boiled rice and freshly chopped parsley or chives just before serving the soup. Rice may also take the place of barley in mutton broth.

**Vegetables.**—Cut raw carrot, turnip, etc., into "matchsticks" or small balls, shred cabbage and slice celery, and cook them separately for 10 minutes in some stock; alternatively, tie them in muslin, to keep them together, and cook them in the soup. Sprinkle the pieces into the individual soup plates or cups before serving.

**Watercress.**—Float leaves on cream soups.

## FISH

For success in cooking fish good-quality fish in a fresh condition is essential. This should have firm flesh, bright eyes, red gills, clear markings, and be free from unpleasant smell. Sea-water fish is divided broadly into two categories, white fish, such as cod, sole, plaice, haddock, whiting, etc., and oily fish, such as herring or mackerel. Fresh-water fish and shell-fish are more expensive, and usually require special attention for cooking and serving.

Most fish can be steamed, poached, baked, grilled, or fried as directed on pp. 805-9. Fish should always be carefully prepared by washing under cold water, removing the head or scales, and trimming the fins and tail. Sole and plaice may be skinned or filleted.

## Fish Pie

1 lb. cooked fish	Salt and pepper
1½ oz. margarine	1 tablespoonful parsley
1 oz. flour	Squeeze of lemon
½ pint milk	Creamed mashed potato

Skin and bone fish and flake finely. Melt 1 oz. fat, stir in flour and cook for a few minutes without browning. Stir in milk and bring to the boil. Add seasoning, parsley, lemon juice, and the fish, put in a fireproof dish and cover with mashed potato. Dot with margarine and heat in a moderately hot oven (400° F.) for about 20 minutes.

## Fish Cakes

Flour	About 1 lb. boiled potatoes
½ pint milk	½ lb. cooked fish
½ pint fish stock	2 teaspoonfuls chopped parsley
Salt and pepper	Fat for frying
A knob of margarine or butter	Egg and bread-crumbs if required
½ teaspoonful mustard	
A few drops of vinegar	

Blend 1 tablespoonful of flour to a smooth cream with the milk, add the fish stock and bring to the boil, stirring. Cook for 2-3 minutes, then season with salt and pepper and beat in the knob of fat and the mustard, blended with a few drops of vinegar. Mix well and cool slightly.

Mash the potatoes, rubbing them through a sieve if necessary, and mix them with the flaked fish and chopped parsley. Bind with the sauce, adding more seasoning if required, then spread the mixture on a plate and allow to cool. Divide into 6-8 portions and shape into flat cakes or croquettes. Dust with flour and fry in a little hot fat until well browned and crisp on both sides, or coat with egg and crumbs and fry in deep fat. Serve with a good sauce, such as parsley, mustard, or anchovy sauce.

## Fried Fish with Tomatoes

8 fillets of flat fish	Button mushrooms
1 egg	Tomato lilies
Brown breadcrumbs	Lemon butterflies
Fat for frying	Parsley

Coat the filleted fish with egg and breadcrumbs. Heat the fat, fry the fish to a golden colour, drain thoroughly, and keep hot. Fry the mushrooms, grill the tomato lilies, put them round the fish and garnish with lemon and parsley. Alternatively, halve the tomatoes and fry them to serve with the fish.

## Baked Curled Whiting

4 medium whiting	Browned breadcrumbs
Fat	Carrot balls
Seasoning	Parsley and lemon

Prepare the fish and remove the eyes. Curl each whiting round, the tail in the mouth or through the eye-sockets. Brush with melted fat, sprinkle with seasoning and fine breadcrumbs. Dot with fat and bake in a greased tin in a moderate oven (350° F.) for about ½ hour. Garnish with carrot balls, parsley, and lemon, and serve with tomato sauce.

## Baked Stuffed Sole

1 large sole	Lemon butterflies
Fish forcemeat	Cucumber cones
A little fat	Duchesse potatoes

Trim the fish, make an incision down centre back and loosen flesh close to the bone on each

side. Stuff with good fish forcemeat and put on a greased baking-tin. Cover with greased paper and bake 20-30 minutes in a moderately hot oven (400° F.). Lift on to a hot dish and garnish with the lemon butterflies, cucumber cones, and duchesse potatoes.

## Baked Stuffed Haddock

1 fresh haddock	Flour
Savoury stuffing	Shavings of margarine

The head of the fish may be removed or not, according to individual taste. If it is left on, the eyes should be taken out. Wash and trim the fish, then dry and stuff it, sewing or skewering the opening to keep the stuffing in place. Curl the fish to form an "S" and put into a greased tin. Dredge lightly with flour, dot with margarine, and bake in a moderately hot oven (400° F.), basting occasionally for about 30 minutes.

## Creamed Fish au Gratin

½ lb. white fish	2 tomatoes
½ pint milk and water	1 oz. margarine
1 small onion	1 oz. flour
A bunch of herbs	2-3 oz. cheese
Salt and pepper	Chopped parsley
1 lb. boiled potatoes	

Place the fish in a saucepan with the liquid, sliced onion, herbs (tied in muslin), and seasoning, and simmer gently for 10-15 minutes, or until the fish is cooked. Lift out the fish, remove any bones and thick skin, and place in flakes in a fireproof dish lined with a layer of sliced, boiled potatoes. Skin and slice the tomatoes and arrange in a layer on the fish, sprinkling with salt and pepper.

Melt the margarine and add the flour to make what is called a "roux." Add the liquor in which the fish was cooked (making up to ½ pint if necessary) and bring to the boil, stirring continuously. Boil for 2-3 minutes, then add half the cheese, season with salt and pepper, and pour over the fish. Sprinkle with the remainder of the cheese and place in a moderate oven (350° F.) to heat through and brown the top. Before serving garnish with chopped parsley.

## Grilled Salmon Steaks

Salmon steaks about 1 in. thick	Lemon
Oil or melted fat	Maitre d'hôtel or anchovy butter
Seasoning	

Wipe the steaks, brush with oil or melted fat, and sprinkle with seasoning. Cook under a hot grill for 10-15 minutes, until the flesh comes away from the bone when tested with a skewer. Serve garnished with lemon and a pat of maitre d'hôtel or anchovy butter on top of each steak.

## Grilled Trout

Clean and dry the fish, split them open and remove the backbone. Brush the trout over with melted fat or olive oil, and season with salt, pepper, and lemon juice. Lay them on a hot grill and cook for 5-10 minutes on each side. Serve at once with cut lemon and watercress, or peas.

## Oysters au Naturel

Fresh oysters	Bread and butter
Salt	Lemon and parsley or cress to garnish
Cayenne pepper	
Lemon juice or vinegar	

Serve the oysters very cold, opened, and on the deep shell. Sprinkle with salt, a touch of Cayenne, and a squeeze of lemon juice or a little best-quality vinegar. Serve with thin slices of bread and butter or with rolls, and garnish with lemon and parsley or cress.

## Fried Oysters (Pigs in Blankets)

Cut thin rashers of bacon in half. Wrap each oyster, previously dried, in a slice of bacon, and fasten together with a tiny wooden skewer. Lay on a towel till the last minute to get entirely dry, and brown very quickly in a hot frying-pan. Place two "pigs" on a square of hot toast, and serve with a little of the liquid from the pan poured over; garnish with parsley and serve at once.

## Dressed Lobster

Twist off the claws and the legs and crack each one carefully, using either a hammer or heavy

weight. Hold the lobster firmly and bend it in order to separate the body from the tail section. Using scissors, then a sharp knife, cut the tail in half lengthways from underside. Remove dark cord. Remove bony part from the body; discard the "dead men's fingers" and stomach, found in head. Leave the tail meat in the shell. Mix the rest with a little mayonnaise, salt, pepper, and a squeeze of lemon juice. Pile on to a bed of lettuce, and serve with watercress, sliced tomato, and cucumber. Garnish with some of the small claws and coral, if present. If preferred, the large claws may be served already cracked so that the flesh can be easily removed.

#### Lobster au Gratin

1 lobster	$\frac{1}{2}$ pint milk and stock
2-3 mushrooms	mixed
1 onion	Salt and pepper
$\frac{1}{2}$ oz. fat	1 teaspoonful browned
$\frac{1}{2}$ oz. flour	breadcrumbs
	Watercress

Cut the lobster in half lengthwise, remove the meat and divide into neat pieces. Peel and slice the mushrooms, and peel, slice, and chop the onion roughly; fry both lightly in the fat. Add the flour, mix thoroughly and pour in the liquid, stirring until the sauce boils and thickens. Season, simmer for several minutes until the onion and mushrooms are tender, then add the lobster meat and a little of the grated cheese. The mixture should be of a thick, creamy consistency. Re-heat the meat in the sauce, pile into the two halves of the lobster shell, sprinkle with the remaining cheese and the breadcrumbs, and brown quickly under the grill or in a hot oven (450° F.) on the top shelf. Serve immediately, garnished with watercress.

#### Creamed Shrimps

$\frac{1}{2}$ pint shrimps	Seasoning
$\frac{1}{2}$ pint white sauce (hot)	Breadcrumbs
1 oz. cheese	

Put the picked shrimps in the white sauce, grate the cheese and add half of it, with seasoning, to the mixture. Place in small fireproof ramekin dishes, sprinkle with the rest of the cheese and a few bread-crumbs, and heat through in a hot oven (425° F.) for about 10 minutes. Serve very hot, garnished with hot shrimps.

#### Prawn Cutlets

4 oz. shelled prawns	A few drops vinegar
1 oz. margarine	A pinch of nutmeg
1 oz. flour	Egg and breadcrumbs
$\frac{1}{2}$ pint milk	Fat for frying
Salt and pepper	Whole prawns to garnish

Chop the prawns. Melt the fat, add the flour, and make a roux. Gradually add the milk and cook the sauce thoroughly. Add all the seasoning, then spread the mixture on a plate and allow to cool. Shape into eight cutlets, and egg and crumb them. Fry in smoking hot fat until golden-brown. Garnish with whole prawns, and serve either hot or cold.

#### Crab Salad

1 cooked crab	1 lettuce
Salt and pepper	Tomatoes
Salad cream	Watercress

Remove the meat from the crab shell, keeping the dark and white meats separate. Season with salt and pepper and add a little salad cream. Arrange the lettuce on a glass dish, put the dark meat in the centre and the white meat around. Garnish with sliced tomatoes, the watercress and the crab legs.

#### Mussels à la Marinière

2-3 dozen mussels	$\frac{1}{2}$ pint mussel liquor
(cooked)	$\frac{1}{2}$ pint milk or wine
1 oz. butter	1 teaspoonful chopped
1 small onion	parsley
1 tablespoonful flour	Pepper and salt

Heat the mussels. Melt the butter in a saucepan, add the onion (very finely chopped), and cook slowly for a few minutes. Stir in the flour and allow it to cook, then add the mussel liquor and milk or wine, and stir until boiling. Allow this sauce to simmer slowly for at least 5 minutes, add the parsley and seasoning and pour over the mussels.

#### Stewed Scallops with Cheese

6 scallops	1 oz. grated cheese
Salt and pepper	Toast snippets and
Lemon juice	lemon to garnish
$\frac{1}{2}$ pint white sauce	

Wash and drain the scallops, discard the beard and the black part, and cut the remainder into quarters. Put into a greased pan, sprinkle with salt, pepper, and lemon juice and pour over the white sauce. Simmer very gently for about 10-15 minutes, until tender, and stir in the cheese. Serve garnished with toast snippets and lemon.

#### Herrings in Oatmeal

2 herrings	$\frac{1}{2}$ teaspoonful salt
1 oz. medium oatmeal	$\frac{1}{2}$ teaspoonful pepper
1 teaspoonful dry mustard	1 oz. dripping

Clean the herrings and split them open, removing the backbone. Mix the oatmeal and seasonings together. Brush the herrings with melted dripping and coat with seasoned oatmeal. Fry or cook under the grill for 5-6 minutes.

#### Soused Herrings

Wash and trim the herrings. Season and roll up from head to tail. Place in a pie-dish and cover with vinegar and water (equal quantities), spiced with 2 cloves, 1 bay leaf, and seasonings. Bake in a slow oven (300° F.) for  $\frac{1}{2}$  hour. Serve hot or cold.

#### MEAT

Roasting is the most popular method of cooking meat, but it should be reserved for good-quality and good-sized joints. Poorer-quality joints braise or pot roast well, while the cheaper cuts of meat are better stewed. Small cuts of meat like chops, fillet steak, cutlet, liver, etc., are usually grilled or fried.

Directions for roasting are given on p. 808, but the following accompaniments can be served with roast meat:

*Beef*.—Yorkshire pudding and horseradish sauce.  
*Mutton*.—Red-currant jelly or onion sauce.  
*Lamb*.—Mint jelly or mint sauce.  
*Veal*.—Forcemeat balls and bacon rolls.  
*Pork*.—Sage-and-onion stuffing and apple sauce.

#### Mixed Grill

This consists of a selection of foods suitable for grilling, such as a chop, kidney and sausages, or a steak, liver and sausages, served with grilled halved tomatoes, mushrooms, chipped potatoes, and maitre d'hôtel butter (see p. 854). Prepare the various items for grilling, and season all meats on both sides with salt and pepper and a little lemon juice, if liked. Brush all the pieces over with melted fat, and start by grilling the foods which require the longest time, so that they are all ready at the same time.

#### Grilled Lamb Chops and Peas

Lamb chops	New carrots
Oil or melted fat	Mint sauce
Green peas	

Skin the chops and trim away any excess fat. Brush them over with oil or melted fat and put them under a hot grill. Cook for a few minutes on one side, then turn the chops over, using two wooden spoons or a palette knife, and cook the other side. Continue to cook, turning them occasionally, and allowing about 8-10 minutes altogether. Decorate the end of each chop bone with a cut paper frill and serve them on a hot dish with green peas and new carrots, and mint sauce served as an accompaniment.

Pork chops must be grilled for 20 minutes at least, and are delicious served with fried apple rings or apple sauce.

#### Pork Chops Baked and Stuffed

Flatten the chops and trim them if necessary, lay them on a baking-dish and cover the lean part of each chop with a layer of sage-and-onion stuffing. Cover with greased paper and bake in a moderately hot oven (400° F.) until the lean is well cooked and the fat crisp and brown—about  $\frac{1}{2}$  hour. Serve with baked tomatoes and apple sauce.

## Boiled Leg of Mutton and Caper Sauce

½ leg mutton	4 medium-sized carrots,
Boiling water	turnips, and onions
Salt and pepper	Caper sauce

Wipe the meat. Have ready sufficient fast-boiling water to cover the joint completely, place it in the pan, and when the water again reaches boiling point, allow it to boil for a few minutes. Then add the seasoning and the vegetables, cut into quarters. Simmer gently until the joint is cooked, allowing 20 minutes to the lb. and 20 minutes over. When cooking is almost complete, prepare the caper sauce, using the liquid from the pot. Serve the meat on a hot dish, put the vegetables round and pour over the caper sauce.

## Brown Stew

½–1 lb. stewing steak	1 oz. flour
1 onion	1 pint stock or water
2–3 carrots	Seasoning
A piece of turnip	A bouquet garni
A stick of celery	Gravy browning, if
1 tablespoonful dripping	necessary

Wipe the meat and cut into neat pieces. Peel the onion and cut into thin rings. Prepare the other vegetables and cut into rings or dice. Melt the dripping in a pan, place half the meat in the fat and fry quickly until it is lightly brown, then turn and fry on the other side; fry the rest of the meat. (If all the meat is put in the pan at once, it will cool down the fat and the frying will be very slow.) Lift the meat out on to a plate, re-heat the fat, add the onion, and fry for a few minutes until lightly coloured. Remove from the fat, then add the flour and fry until browned. Add the liquid gradually, season and bring to the boil. Put in the meat, vegetables, and bouquet garni, cover and simmer gently for about 2–2½ hours. If stewing in the oven, turn the contents of the pan into a casserole and allow to cook gently in a slow oven (325° F.) for 3–4 hours. Before dishing, remove the bouquet garni, re-season and, if necessary, add a few drops of gravy browning to colour. If fat meat is used, the stew sometimes becomes greasy; this can easily be rectified by blending 1 teaspoonful of flour with a little cold water, stirring it into the stew and re-boiling; the flour will then absorb the excess fat.

Brown stew can be varied by: (1) adding potato dumplings; (2) adding 1 tablespoonful of piquant sauce and a clove or garlic to sharpen the flavour. Potatoes can be cooked in the same pot as the stew; they should be peeled and placed whole on top of the stew and cooked for at least an hour. If available, 2–3 mushrooms, a few tomatoes, or a cupful of cooked beans may be added to enrich the flavour.

## Irish Stew

1 lb. middle neck of mutton	Salt and pepper
2 lb. potatoes	Cold water
2 large onions	Chopped parsley

Prepare the meat by wiping thoroughly, removing the marrow and cutting into neat pieces. Cut the potatoes and onions into rings and place alternate layers in a pan, finishing with a layer of potato. Add salt and pepper and sufficient water to half-cover. Bring to the boil and simmer gently for about 2 hours, or until the meat and potatoes are tender.

Pile the meat, gravy, and some of the potatoes in the centre of a hot dish, placing the rest of the potatoes at either end of the dish. Sprinkle with a little chopped parsley.

## Beef Olives

1½ lb. thick beefsteak	1 pint stock
Veal forcemeat	Mashed potatoes
Diced mixed vegetables	1 oz. flour

Cut the meat into slices about ½ in. in thickness, and then into oblongs of about 2½ by 3 in. Spread with the veal forcemeat, roll up, and tie with string. Braise on a bed of vegetables in the seasoned stock until tender—about 1½–2 hours. Remove the string and serve the meat on mashed potato with some of the gravy (thickened flour) poured over.

## Dry Curry of Beef

1 lb. frying steak	1 tablespoonful chutney
1½ oz. dripping	or other pickle
2 onions	1 teaspoonful red-currant jelly
1 small apple	A squeeze of lemon juice
1 dessertspoonful curry powder	Rice

Cut the beef into even-sized pieces. Melt the fat and fry the chopped onions, apple, and curry powder. Add the meat, chutney, jelly, and lemon juice. Mix thoroughly and cook very slowly with the lid on until the meat is tender, stirring frequently. Serve with a border of rice.

## Steamed Meat Roll

Suet-crust pastry	1 carrot
1 lb. beefsteak	Salt and pepper
1 onion or leek	Stock

Make the suet-crust pastry and roll it out. Mince the meat, onion or leek, and the carrot, season with salt and pepper, and moisten with a little stock. Spread this mixture on the pastry, moisten the edges with a little cold water, and roll up. Tie in a floured pudding-cloth, allowing room for the roll to swell, and steam for 3 hours. Serve with a good brown gravy sauce.

Cooked meat and vegetables may be used in the same way, and instead of steaming the roll it may be baked in a moderately hot oven for about 45 minutes and served with gravy sauce.

## Sausage-meat Galantine

1 lb. sausages	2 teaspoonfuls chopped
1 or 2 rashers of bacon	onion or leek
Any pieces of cooked meat, etc. (if available)	½ teaspoonful mixed herbs
1 tablespoonful chopped parsley	Pepper and salt
	Stock or water

Skin the sausages and mince the bacon, and meat if used. Mix with the herbs and seasonings and moisten with a little stock or water. Form into a roll and tie in a floured cloth. Boil for 1 hour. Serve hot, with a good brown sauce and green vegetables. Serve cold, rolled in browned crumbs, with a green salad.

## Braised Ham

½ a ham, either bottom or knuckle end	A bouquet garni
½ a carrot	1 quart stock
1 turnip	3 sliced tomatoes
1 onion	Mushrooms, if liked
	½ pint rich brown sauce

Soak the ham for 12 hours at least, longer if possible. Place in a large pan with the carrot, turnip, onion, and herbs. Add just sufficient water to cover and simmer for 2½–3 hours, according to the size of the joint, then remove from the saucepan and peel off the brown skin. Place the meat in a braising-pan or strong deep saucepan, add the stock, tomatoes, and a few mushrooms, if available. Place in the oven, put on the lid, which should be tight-fitting, and cook for 1–1½ hours, the time depending on the size of the ham. Dish up, strain the stock, and reduce it to half-glaze by boiling. Then brush over the top. Add the brown sauce to the remainder, boil for a few minutes and serve as gravy.

## Meat-and-bacon Roll

4 oz. minced raw meat	1 teaspoonful chopped
2 oz. minced bacon	parsley
2 oz. minced onion or leek	Salt and pepper
½ teaspoonful mixed herbs	A little stock or gravy
	8 oz. suet-crust pastry

Mix together the minced raw meat, bacon, and onion. Add the herbs and season well with salt and pepper, then moisten with a few tablespoonfuls of stock or gravy.

Make the pastry in the usual way. Roll into an oblong about ½ in. in thickness and spread to within ½ in. of the edge with the prepared filling. Moisten the edges and roll up as for jam roly-poly. Roll in greased paper. Tie in a cloth and steam for 2–3 hours. Serve with gravy or a good sauce.

Soak the pickled tongue in cold water for several hours. (If a smoked tongue is used, it will need 12 hours soaking.) Wash the tongue, skewer into shape, put into lukewarm water, bring slowly to the boil, and skim. Add flavouring vegetables and peppercorns, and simmer the tongue very gently until tender: a 6-lb. tongue will need to simmer for 3-4 hours. When tender, take out the tongue, plunge into cold water so that the skin will come off easily, and skin it very carefully. Slip out any bones in the root and cut off remaining gristle. Roll the tongue while still hot into a round cake-tin, fitting it in tightly. Add a little jellied stock, put a weighted cover on top and leave to set for several hours.

### Fried Sweetbreads

1 sweetbread  
Stock or water  
Salt and pepper  
Egg and breadcrumbs

Fat for frying  
Lemon and parsley to garnish

First wash the sweetbread and soak in cold water for 1-2 hours, changing the water occasionally. Put into a pan and blanch, then cover with cold water and remove with the fingers any veins, fat, or skin that will come away without damaging the sweetbread. Put into a pan with a little stock or water and simmer gently for 25-30 minutes. Drain and press between two plates until cold. Slice the sweetbread neatly, season it, and egg-and-crumbs the slices. Fry until golden-brown, then drain and serve garnished with cut lemon and parsley.

### Tripe and Onions

2 Spanish onions  
1½ lb. prepared tripe  
1 oz. butter  
1 oz. flour  
½ pint tripe liquor

½ pint milk  
Seasoning  
A pinch of nutmeg  
Toast

Peel the onions and cook them together with the tripe until both are tender. Then drain, reserving the liquor. Cut the tripe in pieces and chop the onions. Melt the butter in a fireproof casserole, mix in the flour, and then add the tripe liquor, a little at a time. Stir until boiling, add milk, seasoning, onions and tripe, and simmer all together for about 15 minutes, stirring occasionally. Serve in the casserole, garnished with toast cut in pieces.

### POULTRY

The selection of poultry is of prime importance. When buying look for a plump bird with a smooth skin. For roasting the bird must have a flexible breast bone and smooth legs with short spurs. Most poultry is sold ready for the table; if, however, it has not been prepared it should be hung by the feet, somewhere cool, so that air can circulate round it. It should not be hung more than two to three days, according to weather conditions. The plucking is best carried out directly after killing, whilst the bird is still warm, then singe with a lighted taper. Remove the sinews from the legs, cut off the head, and draw after hanging and when required. The liver, gizzard, heart, and neck are used for making stock. Prepare the liver by removing the gall bladder, and the gizzard by cutting through to remove the "bag of grit". Fowls and turkeys are usually stuffed at the neck end, and geese and ducks at the tail end. After stuffing, truss the bird to keep it a good shape. The appropriate stuffings and accompaniments are as follows:

**Turkey.**—Sausage, celery, chestnut, or other forcemeat. Serve with gravy, bread sauce; sausages, bacon rolls, or cranberry sauce.

**Chicken.**—Forcemeat stuffing. Serve with gravy, bread sauce, sausages, fried crumbs, bacon rolls.

**Duck.**—Sage-and-onion stuffing. Serve with gravy, apple sauce, and orange salad.

**Goose.**—Sage-and-onion stuffing. Serve with gravy, and apple sauce.

**Guinea Fowl.**—Serve with watercress, gravy, and orange salad. For roasting times see previous chapter.

### Chicken Casserole

1 chicken  
1 oz. seasoned flour  
1 onion  
Dripping  
1 pint stock or water

Salt and pepper  
A bouquet garni  
½ lb. mushrooms or  
½ lb. tomatoes

Joint the chicken, cut into convenient-sized pieces, and dip in seasoned flour. Cut up the onion finely and fry until golden in the hot dripping. Brown the chicken and put into a casserole with the onions. Stir the rest of the seasoned flour into the dripping and fry until brown, then add the stock or water and stir until boiling. Season well. Pour into the casserole over the chicken and add a bouquet garni and the roughly chopped mushrooms or tomatoes. Put on the lid and cook in a moderate oven (375° F.)

for about 1½ hours, or until the legs of the chicken are tender when pierced with a fork or skewer. Remove the bouquet garni and serve.

### Chicken Maryland

1 prepared chicken  
Seasoning  
Flour  
1 egg

White breadcrumbs  
Dripping  
Milk and stock mixed  
½ lb. sliced mushrooms

Simmer the giblets and neck for stock. Season the jointed bird, dip in flour, then in beaten egg. Roll it in the crumbs and put in a greased tin. Roast in a moderately hot oven (375° F.), basting occasionally, until tender. Make a sauce by stirring a tablespoonful of flour into some of the fat left in the tin, and adding milk and stock. Simmer the mushrooms in the sauce. Serve the chicken with the sauce poured around.

### Chicken Fricassée

1 chicken  
1 onion  
1 stalk of celery  
A bouquet garni  
1½ pints stock or water  
Salt and pepper  
2 oz. margarine

1½ oz. flour  
A squeeze of lemon juice  
A little "top of milk" if available  
Parsley  
Bacon rolls

Joint the bird, cut into convenient-sized pieces, and put into a pan with the sliced onion, chopped celery, bouquet garni, liquid, and seasoning. Cover the pan and simmer gently for about 1½ hours, or until the chicken is tender. Melt the margarine in another saucepan and stir in the flour. Gradually add about 1 pint of the chicken liquor and a squeeze of lemon juice. When boiling stir in a little "top of the milk," if available and season. The sauce should be of a coating consistency. Arrange the cooked chicken in a hot dish, pour the sauce over, and garnish with parsley and small rolls of bacon.

### Chicken Galantine

Allow 12 oz. sausage-meat, some slices of ham (or tongue or bacon), and two hard-boiled eggs to each chicken. Spread some of the sausage-meat on the boned bird, and arrange slices of the ham and the sliced eggs on top. Season, and cover with the rest of the sausage-meat. Fold in both ends of the boned chicken and roll it up tightly. Tie in a clean cloth and simmer in stock for 2 hours. Place the galantine on a dish and press it down by putting a weighted dish on top. When it is cold brush the surface with glaze and decorate with piped butter and aspic jelly.

### Devilled Turkey Legs

Chop off any unsightly length of bone and score the flesh of the legs deeply with a sharp knife, both round and across. Brush with melted butter.

Mix on a plate 1 teaspoonful each of French and English mustard, 2 of finely chopped chutney, a pinch of ground ginger, pepper, salt, Cayenne pepper, and browned breadcrumbs. Spread this mixture over and into the cuts, put the turkey legs aside for an hour, then cook under a very hot grill until crisp and brown. Serve quickly, garnished with water-cress. Pats of butter and some piquant sauce may be served separately.

### Braised Duck

1 duck  
Dripping  
2 rashers of bacon  
1 carrot  
1 onion  
2 sticks celery  
A piece of turnip

A bouquet garni  
Salt and pepper  
½ pint stock  
1 orange  
1 oz. flour  
Watercress

Joint the duck, cut into convenient-sized portions, and fry in a little dripping until brown. Dice the bacon, carrot, onion, celery, and turnip and put at the bottom of a stewpan or casserole. Add the bouquet garni and the fried pieces of duck. Season and add the stock, which should just cover the duck. Cover and cook on top of the stove or in a moderately hot oven (400° F.) until tender—this will take about 1½-2 hours. Put the pieces of duck on to a hot-plate. Strain the liquor and add the grated orange rind and juice of half the orange. Thicken the sauce with blended flour and pour over the duck. Garnish with watercress and pieces of orange.

## Casserole of Pigeons

2 pigeons  
1 tablespoonful flour  
Pepper and salt  
A piece of ham or  
bacon  
1 oz. dripping

Piece of turnip, sliced  
1 stalk of celery, sliced  
1 onion, sliced  
½ pint stock or water  
Bunch of herbs, tied in  
muslin

Prepare the pigeons, cut in halves, and toss in seasoned flour. Dice the ham or bacon and fry until lightly browned, then remove it from the pan. Add the dripping to the pan and fry the pigeons in this until lightly browned, and then remove from the pan. Add the vegetables and sauté for several minutes. Then add the flour, stir in the stock and bring to the boil, stirring. Return the pigeons and the bacon, and add the bunch of herbs (tied in muslin). Cover and simmer gently until the pigeons are tender (about 2 hours), or put into a casserole and cook in a slow oven. Remove the herbs and add more seasoning if necessary. Place a border of mashed potatoes round a hot dish, arrange the pigeons and vegetables in the centre, and pour the sauce over, or, if cooked in a casserole, it may be served without dishing.

## GAME

All wild birds and animals protected by law during certain seasons of the year are known as game. The most common of these are pheasants, partridges, grouse, wild duck, hares and deer. Less commonly eaten in this country are snipe, plover, woodcock, quail, and ptarmigan. The game seasons are roughly from August, September, or October until December, February, or March, although it is now possible to buy frozen or imported game out of season.

Game birds should be hung for a week at least before being plucked and drawn. If cooked too soon game is tough and lacks flavour. The actual length of time for hanging can be judged only by individual taste, but as a guide the bird should be ready when the tail feathers come away easily. Small birds such as snipe and woodcock require less hanging time, and should be roasted undrawn on a piece of toast which is served with the bird.

Directions for roasting are given in the previous chapters, but game can be served with the following accompaniments.

Pheasant	} Gravy, bread sauce, fried bread-crumbs, and game chips
Partridge	
Grouse	
Ptarmigan	
Snipe	} Gravy, fried breadcrumbs, game chips
Plover	
Woodcock	
Quail	
Wild Duck	Gravy, orange salad, game chips

## Pheasant Casserole

1 pheasant	2 rashers of chopped
Seasoned flour	bacon
Fat for frying	Stock
4-6 oz. mushrooms	A little port (optional)
Salt and pepper	Chopped parsley

Joint the bird and dip the pieces in the seasoned flour. Heat the fat in a frying-pan and fry the pieces of pheasant until they are golden-brown, then put them in the casserole, with the sliced mushrooms, the chopped bacon, salt and pepper, and sufficient stock to half-cover the pheasant. A little port wine may be added with the stock, if desired; cook gently in a moderate oven (350° F.) for about 1½ hours. Just before serving, sprinkle the surface with chopped parsley. Serve with creamed or chipped potatoes and orange salad.

## A Salmi of Partridge

Partridges	Little white wine
1 little butter	Stock
Carrot	1 tomato
Onion	A few mushrooms
2 shallots	Croûtons of fried bread
1 tablespoonful flour	

This can be made with either cooked or uncooked birds. If the latter, they should be roasted and left rather underdone, as they will finish cooking in the sauce. Cut each partridge into two or three pieces, according to its size. Remove the skin and the larger bones of the carcass, arrange the pieces in a casserole, and cover whilst

making the sauce. Chop up the scraps, put them into a frying-pan with a little butter, a few small pieces of carrot and onion, and one or two shallots. Fry until brown, then sprinkle with about 1 tablespoonful of flour and brown that also. Moisten with a little white wine and stock, and add a tomato cut in pieces. Cover and cook slowly for 1 hour. Meanwhile cook a few fresh mushrooms, putting the trimmings in the sauce. When the sauce is ready, strain it over the pieces of partridge and let them heat thoroughly, but without boiling. In a salmi the sauce should be thick and velvety and the joints of game should seem to have been cooked with it, and must not appear to be swimming in gravy. Garnish with the mushrooms and some croûtons of fried bread.

## Game Croquettes

½ lb. cold cooked game	Fat for frying
½ lb. creamed potatoes	½ lb. mushrooms
Seasoning	Game chips
Beaten egg	Parsley or watercress
Breadcrumbs	

Remove any bones or pieces of skin from the cold cooked game and mince the flesh finely. Place in a bowl with the creamed potatoes and seasoning, and mix well. Form the mixture into croquettes, coat them with beaten egg and roll them in breadcrumbs. Heat the fat in a pan until smoking hot, then fry the croquettes until they are golden-brown. Drain them carefully, and serve them at once in a hot dish, with grilled or fried mushrooms and game chips. Garnish with parsley or watercress.

## Stewed Venison

(Use the shoulder, breast, and neck for stewing.)

1 lb. venison	Stock
1½ oz. flour	Bunch of herbs, tied in
Salt, pepper, nutmeg	muslin
1 onion	1 dessertspoonful vine-
1½ oz. dripping	gar

Cut the venison in joints and toss in the seasoned flour. Slice the onion. Fry the meat and onion in the hot fat until lightly browned, then stir in any remaining flour, and brown, before adding the stock, bunch of herbs, and vinegar. Cover, and stew gently in the oven or on the top of the stove until tender (2-3 hours). Serve with stewed celery or a green vegetable.

## Jugged Hare

1 hare	Small bay leaf tied in
1-2 oz. dripping	muslin
1 rasher of bacon	4 peppercorns tied in
1½ pints stock or water	muslin
1½ oz. flour, blended	Small blade mace tied
with a little stock	in muslin
1 onion stuck with 2	1 teaspoonful red-cur-
cloves	rant or other sharp
Seasonings	jelly
Bunch of herbs tied in	1 glass port or other red
muslin	wine
	Force meat balls

Skin and paunch the hare, reserving the blood and saving the liver, heart, and kidneys. Wipe the hare and cut into joints. Heat the dripping in a casserole and fry the joints in it with the bacon. When the meat is lightly browned add stock to cover and stir in the blended flour, the onion, seasonings, and herbs.

Cover and cook very gently in a moderate oven, or on top of the stove, until tender (about 3 hours). A few minutes before serving remove the onion and herbs. Stir in the strained blood, the red-currant jelly, and the wine. Reheat without boiling, and serve garnished with forcemeat balls.

## Roast Stuffed Rabbit

1 rabbit	½ oz. flour
Fat bacon	½ pint stock or water
Dripping	Bread sauce

## For the Stuffing

4 oz. breadcrumbs	A squeeze of lemon juice
2 oz. chopped suet	A few drops of piquant
½ teaspoonful thyme	sauce
A little grated lemon rind	Beaten egg or milk to
Salt and pepper	mix

Prepare the rabbit. Wash the heart, liver, and kidneys, put in cold water and bring to the boil.

Strain, chop finely, and mix in a large basin with the other stuffing ingredients. Stuff the rabbit with forcemeat and sew up, leaving the ends of the string loose so that it can be removed after cooking. Cut the sinews in the hind legs at the thigh, bring legs forward and press closely against body; bend forelegs in the same way, and keep all in position with two fine metal skewers or with string. Tie a piece of fat bacon on the back and cover with greased paper.

Roast for about 1-1½ hours, basting every 15 minutes. A quarter of an hour before it is ready remove the paper and bacon, baste well, and remove skewers and string. Drain the surplus fat from the tin, add the flour, brown it, and add the stock or water to make a thick gravy; boil this for 5 minutes and strain it round the rabbit. Serve with bread sauce.

#### Rabbit Pie

1 small rabbit	2 tablespoonfuls chop-
2-3 potatoes	ped parsley
1 onion	½ teaspoonful mixed
1 piece of fat bacon	herbs
Salt	1 bay leaf
4 peppercorns (crushed)	Stock or water
	8 oz. short-crust pastry

Wash the rabbit thoroughly and cut into neat joints, putting aside the head and the ribs for stock. Prepare and slice the potatoes and onion. Fill a pie-dish with alternate layers of rabbit, bacon, and vegetables, sprinkling each with seasonings and herbs. Put in the kidney and heart of the rabbit, the bay leaf, and sufficient liquid to come half-way up the dish. Cover with pastry, making a hole to let out the steam, and decorate with pastry leaves. Bake in a hot oven (450° F.) until the pastry is set and lightly browned, then reduce the heat and cook until meat and vegetables are tender—about 1½ hours in all. Fill up with stock and serve hot.

#### EGG AND CHEESE COOKERY

Both egg and cheese are rich in protein and can be cooked in many different ways to provide a satisfying main course. Cheese should be carefully cooked, otherwise it may become tough and indigestible, grate it finely and avoid boiling cheese sauces. The addition of dry mustard to a cheese dish helps to bring out the flavour.

#### Plain Omelet

½ oz. butter or mar-	3 eggs
garine	Pepper and salt

Melt the fat over a brisk heat and tilt the pan so as to allow the sides to become greased. Whisk up the eggs just sufficiently to mix the yolks and whites thoroughly together, and add seasoning. When the fat is beginning to brown, turn the eggs into the pan. Tilt the pan backwards and forwards and gather the mixture in from the sides as it cooks. When it is thick and creamy pour out the egg mixture evenly over the surface of the pan. Allow it to set for a second or two, then tilt the pan away from you and fold the omelet in three, forming a roll in the pan. Brown it slightly on the underside if preferred. Turn the omelet out on to a heated oval dish. Garnish and serve at once.

#### Ham Omelet

1 oz. butter	4 eggs
2 tablespoonfuls cooked ham	Pepper and salt

Melt the fat in the omelet pan, add the diced ham, and fry until lightly browned. Beat the eggs, season, pour them into the pan over the ham. Allow it to set for a second or two, then tilt the pan away from you and fold the omelet in three, forming a roll in the pan. Brown it slightly on the underside if preferred. Turn the omelet out on to a heated oval dish. Garnish and serve at once.

#### Soufflé Omelet

3 eggs	3 tablespoonfuls water
Seasoning	or milk
	½ oz. butter

Separate the egg yolks and whites. Beat the yolks with a wooden spoon until pale and creamy, add seasoning and liquid and beat again. Whisk the whites very stiffly. Now gently melt the

butter in the omelet pan, without browning. Carefully fold the egg whites into the yolk mixture, avoiding over-mixing. Grease the sides of the pan with the melted fat and pour in the egg mixture. Cook over a moderate heat until golden-brown on the underside, then place the pan in a moderate oven (350° F.) or under the grill and lightly brown the top of the omelet. Run a spatula gently round the edge and underneath the omelet to loosen it, then mark it in halves and double it over. Turn it gently on to a hot plate, garnish, and serve at once.

#### Baked Eggs

Use individual oven-proof dishes of glass or china (ramekin cases) for this dish. Place them on a baking-sheet with a knob of butter in each dish and put in moderately hot oven (400° F.) for 1-2 minutes. When the butter is melted, break a fresh egg into each dish, season with salt and pepper, and return to the oven until just set—5-8 minutes. Serve at once.

#### Scrambled Eggs

2 tablespoonfuls milk	Salt and pepper
½ oz. butter	Buttered toast
2 eggs	

Heat the milk and the butter in a strong saucepan, but do not boil. Beat the eggs, add salt and pepper, and pour into the saucepan. Stir over a gentle heat until the mixture begins to thicken, then remove from the heat and stir until creamy. Pile on to hot buttered toast and serve immediately.

#### Stuffed Eggs

4 hard-boiled eggs	1 teaspoonful may-
½ oz. butter or margarine	onnaise
	A little chopped parsley
	Salt and pepper

Cut the eggs in half crossways and remove a small piece of white from the bottom of each, so that they stand firmly. Mix the yolks with the fat, mayonnaise, parsley, and seasoning, and pipe into the cases. Serve with salad and a good mayonnaise.

#### Scotch Eggs

½ lb. sausages or sausage-meat	Breadcrumbs
3-4 hard-boiled eggs	Fat for frying
2 tablespoonfuls seasoned flour	Parsley
A little piquant sauce	Tomato sauce
Beaten egg	Croûtons of fried bread (optional)

Remove the skins from the sausages and shell the eggs. Pass the eggs through the seasoned flour. Add a few drops of piquant sauce to the sausage-meat and divide equally into 3-4 pieces, according to the number of eggs. Cover each egg with the sausage-meat, doing this as evenly as possible to keep the egg a good shape. Brush over with beaten egg, toss in breadcrumbs, and fry in deep fat from which a very faint blue smoke is rising. As the sausage-meat is raw, it is essential that the frying should not be hurried unduly, and for this reason the fat must not be too hot. When the eggs are golden-brown in colour, remove from the fat and drain. Cut in half width-ways, garnish with a small piece of parsley, and serve with tomato sauce.

The eggs may be placed on croûtons of fried bread.

#### Welsh Rarebit

4 oz. cheese	A pinch of Cayenne
½ teaspoonful dry mustard	pepper
	A little milk
	Hot toast

Grate the cheese and add the mustard, pepper, and enough milk to moisten. Melt this in a double boiler or over gentle heat until it is creamy, and pour on to hot toast.

#### Macaroni Cheese

2 oz. macaroni	Salt and pepper
1 oz. fat	2-3 oz. grated cheese
1 oz. flour	Brown breadcrumbs
½ pint milk	

Boil the macaroni in the usual way and drain. Melt the fat, add the flour, and cook for a minute.

Gradually add the milk and stir until it boils. Add the salt and pepper and the grated cheese, reserving a little. Add the cooked macaroni and pour into a greased au gratin dish. Sprinkle with brown crumbs and the rest of the cheese, and brown under a hot grill.

### Cheese Pudding

6-8 slices bread and 2 teaspoonfuls piquant butter  
2 eggs 4 oz. grated cheese  
A little made mustard 1 pint milk  
Salt and pepper 1 oz. breadcrumbs  
1 chopped onion

Cut the slices of bread into neat pieces and arrange in a pie-dish. Break the eggs in a basin and add the seasonings, finely chopped onion, and the sauce. Beat well and add the cheese, reserving about a quarter of it for the top. Stir in the milk, pour the mixture over the bread and butter in the pie-dish, and allow to soak for about 15 minutes before baking. Mix the remaining cheese and the breadcrumbs together, sprinkle over the top of the pudding and bake in a moderate oven (350° F.) until the mixture sets.

### Cream-cheese Tartlets

3-4 oz. short-crust pastry 1 egg  
1 oz. cream cheese Pepper and salt  
½ pint thick white sauce 1 oz. Parmesan cheese  
½ teaspoonful piquant Paprika pepper  
sauce

Line a number of small tartlet tins with the short-crust pastry. Using a fork, beat together the cream cheese, white sauce, piquant sauce, yolk of egg, and a little pepper and salt to make a creamy consistency. Beat the white of egg until stiff, and fold gently into the mixture. Three-parts fill the lined tartlet tins with the mixture and bake in a moderately hot oven (400° F.) for about 15-20 minutes. Before serving, sprinkle a little grated Parmesan cheese on top and dust with paprika pepper.

### Hot Cheese Soufflé

3 eggs ½ pint milk  
1 oz. butter 3 oz. grated cheese  
1 oz. flour Salt and pepper

Separate the eggs. Melt the butter and stir in the flour, gradually add milk and bring to boil, stirring. Cool slightly; add cheese, seasoning, and egg-yolks one by one, beating well. Fold in the very stiffly beaten egg-whites, and put mixture into a prepared case. Bake in moderately hot oven (400° F.) about 30 minutes, till well risen and brown. Serve at once.

## VEGETABLES

Vegetables, especially greens, should be used as soon as possible in order to retain the maximum food value. When storage is inevitable keep them in a cool, airy place. Prepare the vegetables according to type, and cook by boiling, steaming, braising, baking, or frying (see previous chapter).

### Potatoes

**Boiled.**—Allow these about 20 minutes to cook. For new potatoes a sprig of mint is usually added to the water. Serve glazed with a little margarine.

**Steamed.**—Allow about 30-40 minutes, according to size; then either serve the potatoes mashed or glaze with margarine and sprinkle with parsley.

**Creamed.**—Boil or steam some potatoes until tender, and sieve them or beat well with a fork, adding margarine, milk, and pepper. Serve hot, sprinkled with parsley.

**Roast.**—Cook these in dripping round the meat, or in a separate tin; baste occasionally, and allow about ½-1 hour. The potatoes are sometimes par-boiled first.

**Fried.**—Cut the peeled potatoes into chips or rings and dry them in a tea-towel; then fry in smoking-hot fat to cover them completely a few at a time until golden brown. To make game chips slice the potatoes wafer-thin.

### Duchesse Potatoes

1 lb. hot cooked potatoes "Top" of milk  
1 oz. margarine Salt and pepper  
1 egg Beaten egg to glaze

Sieve the potatoes. Melt the fat in a pan, add the potatoes, and when warm add the beaten egg, about a tablespoonful of creamy milk, and seasoning to taste. Turn on to a floured board and divide into small squares. Place these on a greased baking-tin, brush over with beaten egg, and brown in a hot oven (450° F.). If preferred, force the mixture in the form of rosettes, using a large star pipe. Glaze with egg and bake as above.

### Potato Salad

Lettuce 1 tablespoonful chopped  
½ lb. diced cooked celery  
potatoes 1 tablespoonful chopped  
1 chopped onion raisins  
1 tablespoonful chopped parsley Mayonnaise

Arrange the lettuce-leaves in a dish. Mix all the other ingredients together and arrange on the lettuce.

### Asparagus

Cut off the woody end of the stalks and scrape the white part lightly, removing any coarse spines. Tie in bundles, and place upright in a saucepan of boiling salted water. Boil for 10 minutes, then lay flat and continue cooking until tender—a further 10-15 minutes. Drain very well and untie the bundles before dishing. Serve with melted butter (or margarine) or with Hollandaise sauce.

Asparagus may also be served cold, with a vinaigrette dressing or with mayonnaise.

### Aubergine or Egg Plant

Egg plants should be of uniform purple colour, firm, smooth, and free from blemishes. To prepare them, cut off the stem and calyx, and wipe over. For some dishes the Egg Plants are required to be peeled; for others the skin is left on. They are usually stuffed and baked, sautéed, or fried.

### Beans (Broad)

Shell, and cook in boiling, salted water until tender—20-30 minutes. If liked, serve with parsley sauce.

Towards the end of the season the skins of the beans may be very thick and tough—if this is the case it is well worth removing them before cooking.

When very young and tender, that is, when the pods are only a few inches long and the beans inside very small, the whole pods may be cooked and served, and these make a very delicious dish.

### Beans (French and Runner)

Head, tail, and string the beans, and slice them diagonally. Cook in boiling salted water until tender—15-20 minutes, skimming if necessary. Drain well, then toss with salt and pepper and a knob of butter before dishing.

Young beans may be cooked whole if preferred. Cold cooked French or runner beans are a useful ingredient in salads and hors d'œuvre.

### Creamed Beetroot

1 large or 2 small Salt and pepper  
beetroot 2 teaspoonfuls vinegar  
1 oz. butter Grated horseradish, if  
1 oz. flour liked  
½ pint milk

Cook the beetroot very carefully, preserving its red colour. Skin, and cut into dice. Melt the butter in a pan, and mix in the flour. Add the milk by degrees, and bring to the boil, stirring continuously. Boil for 2-3 minutes, and then add the seasoning and vinegar. Add the cubes of beetroot to the sauce, and heat until the beet is hot through and the sauce coloured pink. Dish and serve at once, sprinkle, if liked, with a little grated horseradish.

### Brussels Sprouts and Chestnuts

Brussels sprouts are frequently cooked with chestnuts. The sprouts should be prepared in the usual way and the shell removed from the chestnuts. Put both in boiling water and boil hard for 10 minutes, then strain both free from moisture, and remove the thin brown skin from the chestnuts. Melt 2 oz. butter to about 1 lb. chestnuts and Brussels sprouts, and stew them in the butter until both are thoroughly tender—about 15 minutes. Serve very hot.

## Scalloped Cabbage

- |  |                                |
|--|--------------------------------|
| 1 quart shredded cabbage                     | 4 oz. diced or shredded cheese |
| $\frac{1}{2}$ pint well-seasoned white sauce | 1 tablespoonful grated cheese  |

Shred fine white cabbage into ribbons, making 1 quart. Cook until tender in boiling salted water, drain well, and put in a greased baking-dish. To white sauce, made with  $\frac{1}{2}$  milk and  $\frac{1}{2}$  liquor from the cabbage, add the diced or shredded cheese. Cook gently until the cheese is melted and whip together until smooth. Pour the sauce over the cabbage, stir together lightly, sprinkle with the tablespoonful grated cheese, and brown in a very hot oven (425° F.) or under the grill.

## Braised Carrots

- |                                |                  |
|--------------------------------|------------------|
| 1 lb. carrots                  | A pinch of sugar |
| $\frac{1}{2}$ oz. butter       | Salt and pepper  |
| $\frac{1}{2}$ pint brown stock | Chopped parsley  |

Prepare the carrots and cut lengthways into neat, even slices, or leave whole if young. Put into a pan of cold water, bring to the boil and strain. Heat the butter and fry the carrots golden-brown. Add half the stock, sugar, and seasoning, and cook gently for  $\frac{1}{2}$  hour, until tender, basting occasionally and adding the rest of the stock if required. Serve on a hot dish with a little of the liquor poured round and sprinkle with chopped parsley. Braised carrots are excellent with meat stews.

## Cauliflower with Cheese Sauce

- |                                 |                   |
|---------------------------------|-------------------|
| 1 large or 2 small cauliflowers | Seasoning         |
| 2-3 oz. grated cheese           | Slices of gherkin |
| $\frac{1}{2}$ pint white sauce  | A few capers      |
|                                 | A few mint leaves |

Cook and drain the cauliflower and put it into an *au gratin* dish, reserving some of the best flower pieces for garnish. Add the cheese to the white sauce, keeping some cheese to sprinkle over the finished dish, if desired. Season the sauce, pour it over the vegetable, and garnish the dish with the reserved pieces; arrange the gherkin slices and capers to resemble flowers, adding the mint leaves.

To make cauliflower *au gratin*, mix pieces of cauliflower with sauce and pour into the dish. Sprinkle with cheese and brown crumbs, and brown in a hot oven (425° F.) or under the grill.

## Braised Celery

Prepare the celery as usual and fry in a little dripping until lightly browned. Add salt and pepper and sufficient stock to half-cover. Cover closely with a lid, and cook gently until tender. Lift the celery on to a hot dish and boil the liquor until of a glazing consistency. Pour over the vegetables and sprinkle with chopped parsley.

## Corn on the Cob

Pick the cobs when they are plump and well formed. Homegrown cobs may ripen to a pale golden yellow, but they are very good to eat when still green. Cook as soon after picking as possible.

Remove the outside leaves, leaving on the inner sheath. Put into boiling salted water and cook until tender; this will take about 12 minutes for fresh young cobs, or up to 30 minutes for older cobs. Drain, remove the sheath, and serve very hot, with butter (or margarine), pepper, and salt.

## Stuffed Cucumber

- |   |                                    |
|---|------------------------------------|
| 1 large straight cucumber                     | $\frac{1}{2}$ pint Espagnole sauce |
| $\frac{1}{2}$ lb. chopped ham or sausage-meat | Croutons of fried bread            |
| Seasoning                                     | Rounds of ham and truffle          |

Skin the cucumber, cut in 2-in. pieces, and take out the seeds with a round cutter or small vegetable knife. Season the meat, add one tablespoonful of the sauce, and pile into the prepared rounds. Braise slowly for about 20 minutes. Dish on croutons of fried bread, put on rounds of ham and truffle as a lid, and pour Espagnole sauce (see p. 354) round.

## Baked Stuffed Marrow

- |  |                                   |
|--|-----------------------------------|
| 1 small marrow   | 1 tomato or a little tomato sauce |
| $\frac{1}{2}$ lb. onions   | $\frac{1}{2}$ teaspoonful sage    |
| $\frac{1}{2}$ lb. scraps of meat (or liver, sausage, bacon, ham, etc.) | Salt and pepper                   |
| 4 oz. dry bread (soaked and squeezed)                                  | A little dripping                 |
|  | Gravy or tomato sauce             |

Cut a wedge-shaped piece off the top of the marrow and scoop out all the seeds: there is no need to peel the marrow. Prepare and chop the onions, put into a basin with the minced meat (or bacon, ham, etc.), the soaked bread, sliced tomato or sauce, and the sage; season well with salt and pepper. Mix well together and fill into the marrow, then replace the lid. Grease a fireproof dish with dripping, put in the marrow, cover, and bake in a moderate oven (350° F.) until tender—approximately 1 hour. Serve with gravy or tomato sauce.

## Stewed Mushrooms

- |                         |                 |
|-------------------------|-----------------|
| 1 lb. mushrooms         | 1 oz. flour     |
| $\frac{1}{2}$ pint milk | Salt and pepper |
| 1 oz. margarine         | Toast           |

Peel the mushrooms and cut into quarters. Add to the milk and bring to the boil. Melt the fat and add the flour. Gradually add the milk from the mushrooms, stirring until the mixture thickens. Season and pour over the mushrooms. Cover and simmer gently for 15-20 minutes. Serve with toast.

## Stuffed Onions

- |                         |                 |
|-------------------------|-----------------|
| Even-sized onions       | Chopped parsley |
| Savoury cheese stuffing | Sauce or gravy  |
| A little margarine      |                 |

After removing the papery outside skins, boil the onions for 30-40 minutes, according to size—do not allow them to become soft. Scoop out the centre portion with a small spoon or pointed knife. Fill the cavity with grated cheese mixed with some sieved dry mustard, breadcrumbs, and a little white sauce; minced bacon, breadcrumbs, and finely chopped sage or any other suitable filling may also be used. Place in a greased fireproof dish, dot the tops with shavings of margarine and bake in a hot oven (425° F.) for about  $\frac{1}{2}$  hour, until tender. Sprinkle the top of each stuffed onion with parsley and serve with a good white sauce, a tomato sauce, or gravy.

## Seakale

Wash well, cut off the ends, and tie into neat bundles. Cook in boiling salted water to which a squeeze of lemon juice has been added (this is to preserve the white colour) until tender—20-30 minutes. Drain well, remove the string, and serve on toast, coated with a good white or Béchamel sauce. Seakale may also be braised or served *au gratin*. Cold, it may be served with vinaigrette dressing or added to a mixed salad.

## Spinach

Wash well in several waters to remove all grit, and strip off any coarse stalks. Pack into a saucepan with only the water that clings to it. Heat gently, turning it occasionally, then bring to the boil and cook gently until tender—about 15 minutes. Drain thoroughly, and reheat with a knob of butter and a sprinkling of salt and pepper. If liked, the spinach may be sieved and one or two tablespoonfuls of white sauce, "top of the milk," or sour cream added to it. Reheat before serving.

## Creamed Spinach and Mushrooms

- |                                |                                  |
|--------------------------------|----------------------------------|
| 2 lb. spinach                  | Nutmeg                           |
| Salt and pepper                | Toast snippets                   |
| $\frac{1}{2}$ lb. mushrooms    | 1 hard-boiled egg (if available) |
| 1 oz. margarine                |                                  |
| $\frac{1}{2}$ pint white sauce |                                  |

Wash the spinach carefully, strip off any coarse stalks, and put the spinach in a pan with only the water that adheres to the leaves. Heat gently, turning occasionally, then bring to the boil. Boil for about 15 minutes, then drain thoroughly, mash finely, and season. Skin and chop the mushrooms and sauté them in the fat. When cooked add them to the white sauce, with a little grated nutmeg and salt and pepper. Make a border of the cooked spinach and pour the mushroom sauce in the middle. Garnish with toast snippets, and if possible with sieved hard-boiled egg.

## Stuffed Tomatoes

- |                                    |                         |
|------------------------------------|-------------------------|
| 4 even-sized tomatoes              | ‡ teaspoonful chopped   |
| 1 oz. chopped ham                  | parsley                 |
| 1 teaspoonful chopped onion        | 1 pinch pepper          |
| ‡ oz. butter                       | ‡ cucumber              |
| 2 tablespoonfuls fresh breadcrumbs | Croutons of fried bread |
|                                    | Sprigs of parsley       |

Wash and dry the tomatoes. Cut a small round from each tomato at the end opposite the stalk, leaving it attached at one side. Scoop out the centre with a teaspoon handle. Sauté the ham and onion in the butter for about 3 minutes. Add the crumbs, parsley, seasonings, and pulp removed from the tomatoes. Fill the tomatoes with this mixture and pile neatly on top. Place the lids over and bake in a moderately hot oven (400° F.) for about 15 minutes. The cucumber garnish can be cooked in the same dish. Wipe the piece of cucumber and cut down in four strips. Wrap these in a buttered paper and bake for 15 minutes. Place the tomatoes on the croutons of fried bread and garnish with parsley and the cucumber.

## Green Salad

- |                               |                       |
|-------------------------------|-----------------------|
| ‡ lb. raw peas                | 1 teaspoonful chopped |
| 1 teaspoonful chopped chives  | mint                  |
| 1 teaspoonful chopped parsley | Mayonnaise            |
|                               | 1 lettuce             |
|                               | 1 bunch watercress    |

Mix the peas, chives, mint, and parsley with the mayonnaise. Arrange in a dish with lettuce leaves round the edge and garnish with sprigs of watercress.

## Summer Salad Bowl

- |                          |   |
|--------------------------|---|
| 2 lettuces               | A few spring onions                       |
| 1 cupful green peas      | 1 teaspoonful chopped                     |
| 1 cupful cooked potatoes | garden herbs (chervil, parsley, tarragon) |
| 2-3 tomatoes             | French dressing                           |

Wash the lettuces carefully, reserving the best leaves for garnishing. Break up the remainder and combine with the peas, diced potatoes, sliced tomatoes, and thinly sliced spring onions. Add the chopped herbs to the French dressing and toss the salad ingredients lightly in it. Line the salad bowl with lettuce-leaves and pile the salad in the centre.

## Russian Salad

- |   |                               |
|---|-------------------------------|
| Cooked mixed vegetables, such as carrots, peas, beans, potatoes, asparagus, turnips, etc. | 2-3 tablespoonfuls mayonnaise |
| A few capers, nasturtium seeds, or pickled cucumber                                       | Freshly chopped parsley       |
|   | Watercress                    |
|   | Aspic jelly, if available     |

Cut the vegetables into small dice or rounds and chop the capers, nasturtium seeds, or cucumber. Mix all the ingredients with mayonnaise and serve in small individual dishes or in a large bowl, garnished with freshly chopped parsley and sprigs of watercress. If some aspic jelly is available, cut it into fancy shapes, or chop and use for garnishing.

## Stuffed Tomato Salad

- |                       |                 |
|-----------------------|-----------------|
| 6 even-sized tomatoes | Spring onions   |
| Cooked peas           | Salad cream     |
| Diced cooked carrot   | Chopped parsley |
| Diced cooked potato   | Lettuce         |

Cut the top off each tomato and scoop out the inside. Mix the cooked peas, carrot, potato, and finely chopped spring onion, and add sufficient salad cream to make the mixture bind together well. Fill the tomato cases with this vegetable salad, and sprinkle a little chopped parsley over the top of each. Place the tomatoes on a glass dish with some small pieces of lettuce. This salad makes a colourful accompaniment to cold meat or sliced meat loaf. If preferred, a potato-salad mixture instead of the mixed vegetables may be used to fill the tomatoes.

## Orange and Watercress Salad

- |                           |                     |
|---------------------------|---------------------|
| 2-3 oranges               | 1 teaspoonful lemon |
| 1 tablespoonful salad oil | juice               |
| 1 dessertspoonful vinegar | Watercress          |
|                           | Small cress         |

Peel the oranges and remove all the white pith; cut them crossways into slices and remove any pips. Mix the salad oil, vinegar, and lemon juice, pour over the oranges, and allow them to stand for a short time before serving. Garnish with watercress and small cress. This salad makes a good accompaniment for hot or cold game dishes; grapefruit may be substituted for the orange, if preferred.

## SAUCES AND STUFFING

Sauces are used to flavour, coat, or accompany various dishes, and are in some cases mixed in with the ingredients to bind them together. The foundation of most sauces in which flour is the thickening agent is the "roux" formed by cooking butter and flour together. The butter is melted and the flour added, and the two stirred together. The liquid is added slowly with constant stirring. The sauce must be stirred and boiled for at least five minutes to ensure thorough cooking of the starch grains. For a brown sauce dripping can be cooked until it is a golden brown. Milk, milk and water, or white stock are used for white sauces; vegetable or bone stock for brown sauces, and fish stock for fish sauces. Careful cooking and constant stirring are essential for a good sauce, and if an exceptionally glossy finish is required, the sauce should be strained through a tammy cloth, which is made from a special woolen material of fine texture. Flavouring or colouring should be added just before serving.

## SAVOURY SAUCES

## Basic White Sauce

- |                           |                                |
|---------------------------|--------------------------------|
| 1 oz. butter or margarine | ‡ pint milk, or milk and stock |
| 1 oz. flour               | Salt and pepper                |

Melt the butter, stir in the flour, then add the liquid gradually, stirring well during the process. Continue to stir until the liquid comes to the boil, then boil slowly for 3-5 minutes. Add seasonings.

*Note:* For a coating sauce, use only ‡ pint milk or stock.

## Sauces Made from the Basic Recipe

**Parsley Sauce.**—Add 2 tablespoonfuls freshly chopped parsley and a dash of vinegar just before serving.

**Anchovy Sauce.**—Add anchovy essence to taste (1-2 teaspoonfuls), omitting salt when seasoning. Add also a drop of pink colouring.

**Cheese Sauce.**—Add 2 oz. finely grated cheese, and season with mustard and a few drops of vinegar or piquant sauce.

**Caper Sauce.**—Add 1 dessertspoonful of chopped capers or pickled nasturtium seeds and 1 teaspoonful vinegar.

**Mushroom Sauce.**—Add 1 oz. of chopped mushrooms to the sauce and cook for 2-3 minutes before serving. If preferred, the sliced mushrooms can be sautéed in the fat when the sauce is being made.

**Egg Sauce.**—To ‡ pint white sauce add 1-2 hard-boiled eggs, finely chopped.

**Onion Sauce.**—To ‡ pint white sauce (made if possible partly from the vegetable liquor) add 1-2 chopped cooked onions.

## Bechamel Sauce

- |                   |                        |
|-------------------|------------------------|
| 1 pint milk       | 8 peppercorns          |
| 1 shallot         | 2 oz. flour            |
| Piece of carrot   | 2 oz. butter           |
| 1 stalk of celery | ‡ pint cream, if liked |
| 1 clove of garlic | Salt and pepper        |
| 1 bay leaf        |                        |

Put the milk, vegetables, garlic, bay leaf, and peppercorns into a pan and bring slowly to the boil. Cover and stand near the fire for a few minutes to infuse. Strain and make a sauce, using the flour and butter in the usual way. When cooked allow to cool slightly, then add the cream and seasoning, reheat, but do not boil.

## Brown Sauce

- |                             |                          |
|-----------------------------|--------------------------|
| 1 small onion               | 1 oz. flour              |
| 1 small carrot              | Seasoning                |
| 1 oz. butter or dripping    | Gravy browning, meat     |
| ‡ pint brown stock or water | cube, or glaze, if liked |

Chop the onion and carrot into small pieces, melt the butter, and fry the vegetables until deep brown

in colour, but do not allow them to burn. Stir in the flour, blend with the vegetables, and continue to cook until the flour is also golden brown. Gradually add the stock, bring to the boil, stirring meanwhile, and simmer gently for 15-20 minutes, and then strain. Season to taste. If the sauce is not deep enough in colour a few drops of gravy browning may be added, or a meat cube or glaze may be used to improve the flavour.

### Espagnole Sauce

2 oz. butter or dripping	1 pint brown stock
2 oz. bacon	1 dessertspoonful mushroom ketchup
1 shallot	A bouquet garni
1 large tomato	Pepper and salt
1 small carrot	
2 oz. flour	

Melt the butter and fry the chopped bacon in it, then fry the sliced vegetables until lightly browned. Add the flour and fry all to a rich golden brown. Add the rest of the ingredients and simmer for 40 minutes, then skim and strain. Reheat the sauce and season it.

Note: A tablespoonful or so of sherry may be added to the sauce just before serving.

### Curry Sauce

½ oz. cooking-fat	½ pint stock
1 tablespoonful chopped onion	Salt
1 tablespoonful chopped apple	Lemon juice
1 teaspoonful curry powder	1 dessertspoonful chutney
½ oz. flour	1 teaspoonful table sauce
	1 tablespoonful sultanas

Melt the fat and fry the onion lightly, then the apple, and finally the curry powder and flour. Add the stock gradually and season with salt, boil and skim, then add the lemon juice, chutney, table sauce, and sultanas. Put on the lid and simmer for about 1 hour, stirring frequently. Strain if required.

### Mustard Sauce

1 oz. margarine	½ pint water
½ oz. flour	2 tablespoonfuls vinegar
½ teaspoonful dry mustard	Pepper and salt

Melt the fat and fry the flour and mustard lightly. Add the water gradually, and then the vinegar and seasoning. Stir and boil gently for 3-5 minutes.

### Hollandaise Sauce

2 tablespoonfuls water or stock	2 oz. margarine
1 dessertspoonful tarragon vinegar	Salt and pepper
2 egg yolks	1 dessertspoonful lemon juice

Put the water or stock, vinegar, and yolks of eggs into a basin and stand the basin in a saucepan of hot water. Whisk over heat until the sauce thickens, then draw the saucepan to one side and add the fat in small pieces, stirring well. Season to taste, and add the lemon juice. The sauce must not boil, or it will curdle.

### Mock Tartare Sauce

Small pieces of carrot, turnip, onion, and celery	1 oz. margarine
A blade of mace	1 oz. flour
2 cloves	1 egg
1 bay leaf	½ a lemon
6 peppercorns	1 teaspoonful chopped parsley
½ pint milk or milk and water	½ tablespoonful chopped pickles
	Salt and pepper

Allow the vegetables and herbs to infuse slowly in the liquid for 20-30 minutes, then strain. Melt the margarine, stir in the flour, and fry for a minute or two without browning. Beat in the flavoured milk, adding it a little at a time to prevent lumps forming, then bring to the boil, stirring well. Allow to cool slightly, then beat in the egg and cook for a further few minutes. Add the lemon juice, the chopped parsley, chopped pickles, and seasoning to taste.

### Robert Sauce

2 oz. butter	A few peppercorns
2 onions	Salt and pepper
1 tablespoonful flour	Mustard
½ pint brown stock	Vinegar
Bunch of herbs	Lemon juice
Bay leaf	

Melt the butter and fry the sliced onions in it over gentle heat until golden brown—about 10 minutes. Stir in the flour, to form a roux, then gradually add the stock and bring to the boil, stirring. Add the herbs, bay leaf, and peppercorns tied in muslin and season with salt. Cover and simmer for about ½ hour, then remove the bag of herbs and stir in the mustard, vinegar, and lemon juice to taste, with more salt and pepper if necessary. Serve with goose, pork, veal, or steaks.

### Tomato Sauce

1 small onion	½ pint stock
A piece of carrot	1 oz. flour
½ lb. tomatoes	Seasoning
1 bay leaf	½ oz. dripping or margarine
A little milk	
A bunch of herbs	

Prepare the vegetables, and cut into small pieces. Place with the tomatoes and the fat in a strong pan and heat gently, stirring, until the fat is absorbed. Add the herbs and the stock and simmer for about ½ hour, then rub through a fine sieve. Add the flour blended to a smooth cream with a little milk, season and cook the sauce for a further 2-3 minutes, stirring.

### Apple Sauce

2 lb. apples
1-2 oz. butter or margarine
Sugar, if required
Lemon juice, if required.

Choose good cooking apples, peel and slice with a stainless-steel knife, then cook gently to a pulp in a covered pan. Beat with a wooden spoon until smooth, and add the butter. Sugar may be added if liked, but a tart apple sauce is just the right accompaniment to a goose or duck. On the other hand, if the apples are sweet, a little lemon juice may be added.

### Bread Sauce

½ pint milk or milk and vegetable stock mixed	A small blade of mace
1 teaspoonful chopped onion	2 oz. breadcrumbs (or stale bread soaked and squeezed)
1 clove	Salt and pepper
	A knob of margarine

Put the liquid into a pan with the onion, clove, and mace, and allow to infuse for about ½ hour. Strain and add the breadcrumbs, seasoning, and the knob of margarine. Leave in a very warm place at the side of the stove for 15 minutes, and make very hot before serving.

### Horseradish Cream

1-2 tablespoonfuls grated horseradish	Cream or evaporated milk
1 tablespoon vinegar	Salt, pepper, and sugar

Soak the grated horseradish in the vinegar for 10-15 minutes. Stir in enough cream or evaporated milk to give the desired consistency, and season with salt, pepper, and sugar.

### Maitre D'Hôtel Butter

1 oz. butter	1 teaspoonful lemon juice
1 teaspoonful finely chopped parsley	Salt and pepper

Mix all the ingredients thoroughly into a creamy paste, using a fork or wooden spoon. Shape into pats and make very cold. Serve with grills, etc.

### Mint Sauce

2 tablespoonfuls chopped mint	1 tablespoonful boiling water
1 teaspoonful sugar	1½ tablespoonfuls vinegar

Strip the mint from the stalks and chop it finely. Put the sugar and boiling water in a sauce-boat and stir until dissolved. Add the mint and stir in vinegar to taste.

## Cranberry Sauce

Pick and wash 1 lb. cranberries and put them into a stewpan with 1 teacupful of water. Stew until reduced to a pulp, bruising them well with the back of a wooden spoon. Then add  $\frac{1}{2}$  lb. sugar, and a little port wine, if desired.

## SWEET SAUCES

## Basic White Sweet Sauce

- |                                |                          |
|--------------------------------|--------------------------|
| $\frac{1}{2}$ -1 oz. margarine | 1 teaspoonful sugar      |
| $\frac{1}{2}$ -1 oz. flour     | Vanilla essence or other |
| $\frac{1}{2}$ pint milk        | flavouring               |

Melt the margarine, stir in the flour to form a roux, and cook for 1-2 minutes without browning. Add the milk a little at a time, stirring well to keep the mixture smooth. Bring to the boil, stirring all the time, and cook for 2-3 minutes, beating the sauce to make it smooth and glossy. Sweeten and flavour to taste and use as required.

## Sweet Sauces Made from the Basic Recipe

**Chocolate Sauce.**—Add 1 tablespoonful of cocoa and a few drops of vanilla essence. Sweetened chocolate powder may be used in place of cocoa, in which case sugar will not be needed.

**Lemon Sauce.**—To the cooked sauce add lemon juice or substitute and a drop or so of lemon essence. A little extra sugar may be needed in this sauce.

**Orange Sauce.**—Use finely grated orange rind to flavour the sauce.

## Butterscotch Sauce

- |                                  |                             |
|----------------------------------|-----------------------------|
| 3-4 oz. granulated sugar         | $\frac{1}{2}$ oz. margarine |
| $\frac{1}{2}$ pint boiling water | 2 teaspoonfuls flour        |
|                                  | $\frac{1}{2}$ pint milk     |

Put the sugar into a thick saucepan and heat gently until it caramelises; shake the pan during cooking to prevent uneven browning, but do not stir. When quite liquid and of a good brown colour, remove from the heat, cool slightly, and add the boiling water by degrees. Return to the heat and simmer until caramel is dissolved. Make a white sauce with the other ingredients and stir in the dissolved caramel. Boil for a further 2 minutes and serve hot or cold.

## Custard Sauce

- |                         |                     |
|-------------------------|---------------------|
| 2 teaspoonfuls flour    | 1 teaspoonful sugar |
| $\frac{1}{2}$ pint milk | Vanilla essence     |
| 1 egg                   |                     |

Blend the flour to a smooth cream with a little milk. Heat the remainder, and when hot add to the blended flour, stirring. Cool slightly, then add the egg and heat gently to cook the egg without curdling. Add sugar and vanilla essence to taste. If the sauce is to be served cold, cover while cooling to prevent skin from forming, and heat occasionally.

## Chocolate Sauce

- |   |                          |
|---|--------------------------|
| $\frac{1}{2}$ oz. unsweetened chocolate | Pinch of salt            |
| $\frac{1}{2}$ pint water                | $\frac{1}{2}$ oz. butter |
| 1 teaspoonful cornflour                 | 2 oz. sugar              |
|   | Vanilla essence          |

Break up the chocolate, add half of the water, and dissolve over gentle heat. Mix the cornflour and salt to a smooth cream with a little of the remaining cold water, heat the rest and, when it is boiling, pour it on to the blended cornflour, stirring. Return it to the pan and bring to the boil, stirring. Add the dissolved chocolate, butter, and sugar, and cook for 4-5 minutes, stirring well. Lastly, add a few drops of vanilla essence.

## Jam Sauce

- |  |                         |
|--|-------------------------|
| $\frac{1}{2}$ teaspoonful cornflour or arrowroot | 2 tablespoonfuls jam    |
| $\frac{1}{2}$ pint water                         | A little lemon juice    |
|  | Colouring, if necessary |

Blend the cornflour or arrowroot with a little water. Add the rest of the water, bring to the boil, and allow to cook for about 2 minutes. Stir in the jam, and add the lemon juice, and tint, if necessary, with a little colouring. Strain before serving.

## Syrup Sauce

- |                        |                               |
|------------------------|-------------------------------|
| 4 tablespoonfuls water | 2 tablespoonfuls golden syrup |
| Juice of half lemon    |                               |

Mix all the ingredients together and boil rapidly for a few minutes.

## Marshmallow Sauce

- |                        |                              |
|------------------------|------------------------------|
| 4 oz. granulated sugar | Few drops of vanilla essence |
| 3 tablespoonfuls water | Colouring                    |
| 8 marshmallows         |                              |
| 1 egg white            |                              |

Dissolve the sugar in the water, then boil together for about 15 minutes. Add the marshmallows, cut into small pieces with scissors. Beat the egg white very stiffly, then gradually fold in the marshmallow mixture. Add vanilla and enough carmine or cochineal to tint pale pink. Serve with ice-cream.

*Note:* Peppermint may be used instead of vanilla to flavour; in this case colour the sauce pale green.

## Melba Sauce

- |                                    |                                       |
|------------------------------------|---------------------------------------|
| 4 tablespoonfuls red-currant jelly | 2 teaspoonfuls arrowroot or cornflour |
| 3 oz. sugar                        | 1 tablespoonful cold water            |
| $\frac{1}{2}$ pint raspberry purée |                                       |

Mix together the jelly and sugar and the raspberry purée, and heat until boiling. Blend the arrowroot or cornflour with the cold water and add to the raspberry mixture. Continue cooking until the mixture becomes thick and clear, stirring all the time with a wooden spoon. Strain and cool.

*Note:* This is excellent to serve with peach melba and other sundae.

## Brandy Butter or Hard Sauce

- |                    |                          |
|--------------------|--------------------------|
| 2 oz. butter       | 1 dessertspoonful brandy |
| 2 oz. castor sugar |                          |

Beat the butter and sugar to a white cream, then gradually beat in the brandy. Leave in a cool place until required; serve piled up in a fancy dish.

## STUFFINGS

## Sage-and-onion Stuffing

- |                             |  |
|-----------------------------|--|
| 2 large onions              | 4-5 sage leaves or 2 teaspoonfuls dried sage |
| Boiling water               | $\frac{1}{2}$ teaspoonful salt               |
| $\frac{1}{2}$ -1 oz. butter | $\frac{1}{2}$ teaspoonful pepper             |
| 4 oz. breadcrumbs           |  |

Put the prepared onions into cold water, bring to the boil and cook for 5 minutes, then strain off the water, cover with fresh boiling water, and cook until tender. Drain well and chop finely, then add the butter, crumbs, chopped sage, and seasoning, and mix well together. Use for stuffing goose and duck, or to serve with pork.

## Sausage Stuffing

- |                               |                                       |
|-------------------------------|---------------------------------------|
| 1 large onion                 | $\frac{1}{2}$ teaspoonful mixed herbs |
| 1 lb. pork sausage meat       | 4 tablespoonfuls fresh breadcrumbs    |
| 1 oz. dripping                | Seasoning                             |
| 1 teaspoonful chopped parsley |                                       |

Mix the chopped onion and the sausage meat, and sauté them in the dripping for a few minutes. Mix in the other ingredients and use as required.

## Chestnut Stuffing

- |                                  |                               |
|----------------------------------|-------------------------------|
| 1 lb. chestnuts                  | A little grated lemon rind    |
| $\frac{1}{2}$ pint stock or milk | Salt and pepper               |
| 2 oz. ham or bacon               | 1 teaspoonful chopped parsley |
| 1 teaspoonful sugar              | 1 egg                         |
| 1 oz. margarine                  |                               |

Make a slit in both ends of the nuts and boil in water for 10 minutes, then skin them. Put them into a pan with stock or milk to cover, and simmer gently until tender and mash or sieve them. Pound with the finely chopped ham or bacon, add the crumbs, parsley, melted fat, lemon rind, season with salt and pepper, add sugar, and bind with the beaten egg. Use to stuff turkey, chicken, etc.

## Veal Force meat

2 oz. suet	‡ teaspoonful mixed
1-2 oz. ham or bacon	herbs
4 oz. breadcrumbs	Rind of ‡ lemon
2 teaspoonfuls parsley	Salt and pepper
	Beaten egg

Chop the suet and the ham or bacon finely and mix with the crumbs; and chopped parsley, herbs, and grated lemon rind. Season, and add enough beaten egg to bind. Use for stuffing veal, chicken, rabbit, hearts, etc., or as forcemeat balls.

## Oyster Stuffing

18 sauce oysters	A pinch of mace
6 oz. breadcrumbs	Salt and Cayenne
1 dessertspoonful parsley	2 oz. suet or 1‡ oz. butter
Grated ‡ lemon rind	1 egg

Beard and cut up the oysters, simmer the beards in the oyster liquor to extract the flavour, then strain. Mix dry ingredients and fat, add the oysters, the lightly beaten egg, and oyster liquor to moisten. Use for stuffing the breast of a boiled turkey. Small tinned oysters may be used for this stuffing.

## Fish Force meat

3 oz. breadcrumbs	2 teaspoonfuls chopped
1 oz. chopped suet or melted margarine	parsley
Grated rind of ‡ lemon	Salt and pepper
‡ teaspoonful dried herbs	Egg or milk

Mix all the ingredients together, adding sufficient beaten egg or milk to bind.

## PASTRIES

A few basic rules should be followed for successful pastry making. Working conditions must be cool, and a hot oven is essential. Handle the pastry as little as possible, and measure the ingredients accurately. Avoid stretching the pastry during the rolling. The richer puff and flaky pastries are improved if left in a cool place between rollings, and again before baking. The richer the pastry, the hotter the oven must be.

## Suet Crust

8 oz. flour
1 teaspoonful baking-powder
‡ teaspoonful salt
3-4 oz. chopped or prepared suet
Cold water to mix

Mix flour, baking-powder, salt, and suet together, add cold water to give a light elastic consistency, and handle as little as possible. Turn on to a floured board, knead very lightly, and use as required.

## Dumplings

Roll the dough of suet-crust pastry into balls and add to boiling soups, stews, etc., allowing 20-25 minutes, according to size.

## Syrup Layer Pudding

8 oz. suet crust	1 oz. breadcrumbs
1 lemon	4-6 oz. golden syrup

Make the pastry, adding the grated lemon rind to the flour. Mix the breadcrumbs and lemon juice with the syrup. Divide the pastry into six pieces, graduating in size. Put 1 tablespoonful of the syrup mixture into the bottom of a greased basin. Roll the smallest piece of pastry into a round and place on top of the syrup. Cover with a tablespoonful of syrup and then the next largest piece of pastry, rolled to a round, repeating till the pastry is used up and the basin two-thirds full. Cover with greased paper and steam 2½-3 hours. Turn out on to a hot dish and serve at once. Black treacle may be used in place of syrup, or a mixture of both.

## Short-crust Pastry

8 oz. flour	4 oz. fat
A pinch of salt	Cold water

Sieve the flour and salt into a basin. Add the fat, cover it with flour, and then rub the two together with the tops of the fingers until the mixture resembles breadcrumbs. Lift up the flour and fat in the hands while doing this and

let the cold air mix with them. Then make a hollow in the centre, and add cold water very gradually with the left hand while continuing to mix with the right. Add just sufficient water to make a stiff dough; if the pastry is made too moist, it will not be short. Turn the pastry on to a floured board and knead it lightly with the hand until it is free from cracks; then roll it out to the thickness required.

## Cornish Pasties

6 oz. raw potato	Salt and pepper
‡ lb. lean raw steak or mutton	2-3 tablespoonfuls cold water
1 tablespoonful chopped onion	1 lb. short-crust pastry
	Yolk of egg or milk

Wash and peel the potatoes and cut into dice. Mix with the meat (cut up very small or minced), the finely chopped or minced onion, seasoning, and water. Roll out the pastry thinly and cut into rounds about the size of a saucer. Wet the edges of the pastry and put a tablespoonful of the meat mixture on each round. Fold over, press the edges of the pastry well together, and flute with the fingers. Stand the pasties upright on a baking-sheet, brush over with a little beaten egg or milk and bake in a hot oven (425° F.) till the pastry begins to brown, then reduce to a moderate heat (350° F.) and continue cooking until the meat is tender—about 1 hour in all.

## Apple Pie

1‡ lb. apples	‡ lb. short-crust pastry
2 oz. sugar	Milk or egg white to glaze
Cold water	

Peel, core, and slice the apples. Half-fill a dish with fruit, then add sugar, the rest of the fruit, and water to cover the bottom of the dish. Roll out the pastry 3 in. wider and longer than the pie-dish. Cut off strips 1 in. wide, moisten the edge of the dish with water, and lay the pastry strips on the edge of the dish; press in place. Moisten the pastry strip with water. Lift the piece of pastry on the rolling-pin and lay it over the pie-dish, taking care not to stretch it. Press the edges in place and trim them with a sharp knife. Decorate the edges of the pie and brush over with milk or white of egg. Bake near the top of a hot oven (425-450° F.) for 20 minutes, then remove to a lower part of the oven and continue cooking until the fruit is cooked.

## Bakewell Tart

4 oz. short-crust pastry	1 egg
Raspberry jam	2 oz. ground almonds
2 oz. butter or margarine	1-2 drops almond essence
2 oz. sugar	Icing sugar

Line a flan ring or sandwich tin with the pastry and spread with a layer of raspberry jam. Beat the fat and sugar together until soft and creamy. Add the beaten egg by degrees, beating very thoroughly. Stir in the ground almonds and a drop or two of almond essence and spread over the jam in the pastry case. Bake in a moderately hot oven (400° F.) for 30-40 minutes, until the tart is well risen and brown and the filling is set. Dredge with icing sugar.

## Custard Tart

4 oz. short-crust pastry	‡ pint milk (short measure)
1 egg	
‡ oz. sugar	Nutmeg

Line a fireproof baking-plate with the pastry. Beat the egg and sugar together and pour on the hot milk, stirring meanwhile. Strain into the prepared pastry case and grate a little nutmeg over the mixture. Bake in a hot oven (425° F.) for about 10 minutes, until the pastry is set, and then reduce the heat and continue to bake in a moderate oven (375° F.) until the custard is set.

## Lemon Meringue Pie

4 oz. short-crust pastry	1‡ oz. sugar
1 level tablespoonful cornflour	1 lemon or 2 tablespoonfuls
4 tablespoonfuls cold water	squash
	1 egg

Line a flan-ring or pie-plate with the pastry and decorate. Prick the bottom and bake "blind."

Meanwhile, blend the cornflour with the water, add the sugar, lemon juice or squash, and grated lemon rind. Bring to the boil in a small saucepan, stirring well, and boil for 2 minutes. Allow to cool slightly, then stir in the egg-yolk and pour into the pastry case. Whip the white of egg very stiffly, fold in a little sugar, and pile on top. Bake in a moderate oven (375° F.) for a few minutes, until a light golden-brown.

## Syrup Tart

6 oz. short-crust pastry    2 oz. breadcrumbs  
3-4 tablespoonfuls    Juice of  $\frac{1}{2}$  a lemon  
golden syrup

Line a sandwich tin or a fireproof plate with the pastry, prick the bottom and place breadcrusts on it to prevent the pastry rising. Bake in a hot oven (450° F.) for about 15 minutes. Remove from the oven, pour in half the syrup, sprinkle on the breadcrumbs, add the lemon juice and the rest of the syrup. Decorate with strips of pastry and bake in a moderately hot oven (400° F.) for 20 minutes.

## Flaky Pastry

8 oz. flour    A good squeeze of  
 $\frac{1}{2}$  teaspoonful salt    lemon juice  
3 oz. lard    Cold water to mix  
3 oz. butter or mar-  
garine

Sieve the flour and salt into a basin. Divide the fat into four portions, using half-lard and half-butter in each portion. Rub one portion of fat into the flour until it is as fine as breadcrumbs and mix to a soft dough, using lemon juice and water. Knead lightly and roll out into a long strip. Put one-third of the remaining fat in small flakes over two-thirds of the pastry, taking care not to put it too close to the edges. Fold the pastry in three, the plain part being folded over the fat. Seal the edges of the pastry with a rolling-pin and half-turn it to bring the folded edges to the sides. Press firmly and again roll out into a long strip. Repeat this process twice, using up the remaining two-thirds of fat. Roll out and fold once more, and allow the pastry to stand in a cool place until required.

## Sausage Rolls

Roll some flaky (or rough puff) pastry rather thinly and cut this into strips about  $3\frac{1}{2}$  by 5 in. Divide a raw sausage into four or six pieces and roll the pieces to the required shape. Place a piece of sausage across one end of each strip of pastry, damp the edges, fold the rest of the pastry over, seal the edges neatly, and glaze if required. Bake in a hot oven (450° F.) for 20-30 minutes.

If larger rolls are needed, the sausages may be semi-cooked (prick and bake), left till cold, and then placed whole on the pastry. Brush the tops with beaten egg and bake as above.

## Prawn Patties

8 oz. flaky pastry     $\frac{1}{2}$ - $\frac{1}{2}$  pint white sauce  
Egg to glaze    Parsley  
 $\frac{1}{2}$  pint picked prawns    Watercress

Roll out the pastry to  $\frac{1}{4}$  in. in thickness and cut it out with a fluted pastry cutter. Using a smaller cutter, mark the centre of each round, cutting about half-way through the pastry. Glaze the top with a little beaten egg and bake in a hot oven (450-475° F.) for 15-20 minutes, until well risen and golden-brown. Carefully take out the round "lids." Mix the prawns with enough well-flavoured white sauce to bind them together, and fill the patties with this mixture. Replace the "lids" if desired. Garnish the patties with parsley and watercress, and serve them either hot or cold, with a few large prawns arranged to decorate the dish.

## Eccles Cakes

3 oz. flaky (or rough    1 oz. chopped candied  
puff) pastry    peel  
4 oz. cleaned currants    1 oz. sugar  
Nutmeg and spice to    1 oz. butter  
taste    White of egg to glaze  
Sugar to dredge

Roll the paste to  $\frac{1}{4}$  in. thick and cut into rounds about 4" in diameter. Mix the other ingredients and place a spoonful in the centre of each round.

Damp the edges and draw them together, forming a ball-like shape. Turn the smooth side uppermost, flatten into a round, and cut lightly, marking the top into squares, so that the currants show. Brush with white of egg, sprinkle with sugar, and bake in a hot oven (450° F.) for about 20 minutes.

## Mince Pies

12 oz. flaky pastry    Beaten egg  
Mince-meat    Icing sugar

Divide the pastry in half and roll it out thinly. Cut rounds of pastry large enough to fit some patty tins and put about 2 teaspoonfuls of mince-meat in each. Roll out the rest of the pastry and cut out slightly smaller rounds for the lids. Damp the edges of the pastry lining the patty tins and press on the tops. Flake up the edges with a knife, and snip the top of each, using scissors. Brush the top of each mince pie with beaten egg, and bake in a hot oven (450-475° F.) for 25-30 minutes. Dredge the tops with icing sugar, and serve the pies hot or cold, as preferred. Short-crust, rough puff, or puff pastry may also be used, and fruits, such as sliced apples or raspberries, make a variation in filling.

## Rough Puff Pastry

8 oz. flour    2-3 oz. lard  
 $\frac{1}{2}$  teaspoonful salt     $\frac{1}{2}$  teaspoonful lemon  
2-3 oz. butter or    juice  
margarine    Cold water

Sieve the dry ingredients into a basin, and add the fats, cut into pieces the size of a small nut. Add the lemon juice, mix into a dough with cold water, and turn on to a floured board. Roll out into a long, narrow strip, always rolling with a forward movement and not too heavily. Fold in three, turn the pastry half-round, bring the join to the right-hand side, seal the edges, and roll again. Repeat this until the pastry has had four turns. (A roll and a fold is called "a turn.") Cool the pastry thoroughly before using; if wrapped in a floured cloth or greased paper it can be kept overnight.

This pastry is useful for meat pies and savoury pastries of all kinds.

## Puff Pastry

8 oz. butter    A squeeze of lemon  
8 oz. flour    juice  
Salt    Cold water

This pastry, when well made, consists of innumerable thin layers which melt in the mouth, and in both appearance and taste it is superior to any other type. Its characteristic lightness depends on the amount of cold air enclosed by the special method of making, and the expansion of that air during the baking.

Butter gives the best results, but a mixture of two-thirds margarine and one-third lard may be used. If butter is used, it should first be washed, to remove all salt and butter-milk. Put it into a basin under a tap of cold running water, heat the hands in hot water and chill them in cold, then squeeze the butter in the water until of a waxy consistency and easy to handle. Then dry it in a lightly floured cloth and pat it until every drop of water has been expelled.

Sieve the flour into a basin, add a pinch of salt, then take a piece of the butter about the size of a walnut and rub it into the flour with the fingertips. Make a well in the centre, put in a squeeze of lemon juice, which helps to lighten the pastry, and add sufficient cold water to form a dough. The aim should be to get both the dough and the butter of the same consistency.

Form the dough into one lump and turn it out on a lightly floured board. Knead vigorously for about 10 minutes, until it is smooth and velvety and no longer sticks to the fingers. When it is smooth and elastic, take the rolling-pin and roll it out into a thin square or round. Shape the remainder of the butter into a flat cake and place it in the centre. Fold over the sides of the dough so as to enclose the butter completely, at the same time leaving room for the spread of the butter when rolling. Pat down with the rolling-pin and roll out into a long narrow strip. Now fold the pastry in three, folding the first flap from you and the second towards you. Then turn the

pastry half-way round, bringing the folds to the right-hand side.

Press the edges firmly with the rolling-pin, to enclose all the air possible; this finishes what is called one "turn" in pastry-making. Puff pastry requires seven "turns" or rollings in all, but as too much rolling at one time would make it too soft, it has now to be put aside in a cool place for at least  $\frac{1}{2}$  hour, covered with greaseproof paper or with muslin wrung out in cold water. Bring it out again on to the board and give it two turns in exactly the same way as the first one. Again lay it aside, and repeat this twice more, until the pastry has had its seven turns in all.

The baking of puff pastry requires as much care and judgment as the making. The secret of success lies in having the pastry cold and the oven hot. The temperature should be from 450° to 500° F. to begin with, and when the pastry has risen its full height, the heat may be reduced slightly to allow it to finish cooking.

Puff pastry is used for any dish requiring a very light pastry, such as *vol-au-vent* patties, small French pastries, mince pies, etc.

#### Chicken Vol-au-vent

8 oz. puff pastry	$\frac{1}{2}$ pint white coating
Beaten egg	sauce
6 oz. diced cooked chicken	2 oz. mushrooms
	Cress and parsley

Roll out the pastry to about 1 in. in thickness and cut into a round, using a large cutter or a saucer. Using a smaller cutter or a knife, mark another circle inside, to form a lid. Make some decorative cuts around the top edge of the pastry and brush it with a little egg. Bake in a hot oven (475° F.) for 30–35 minutes, covering the top of the pastry if it tends to become too brown. When it is cooked, remove the lid and take out any soft dough inside. Heat the diced chicken in the white sauce and fill the *vol-au-vent* case. Serve garnished with grilled mushrooms, and with cress and parsley.

#### Jam Puffs

Puff pastry	Egg white
Jam	Castor sugar

Roll the pastry thinly and cut it into squares. Put a little jam on one side, fold the pastry over to form a triangle and seal the edges firmly. Brush over with egg white and sprinkle with sugar. Bake in a hot oven (475° F.) for 10–15 minutes.

#### Vanilla Slices

6 oz. puff (or flaky) pastry	Vanilla essence
Mock cream, cream, or thick custard	Raspberry or strawberry jam
	White glacé icing

Roll the pastry  $\frac{1}{2}$  in. thick and form into a strip 4 in. wide. Cut into oblong pieces about 1 $\frac{1}{2}$  in. wide and bake in a hot oven (475° F.) for 10 minutes. Allow the slices to become quite cold, then sandwich two or three of them together with jam and the mock cream, cream, or thick custard, which has been flavoured with vanilla essence. Top the slices with a little white glacé icing, made according to directions. Serve these pastries as a cold dessert, or for tea.

#### Choux Pastry

$\frac{1}{2}$ pint water	2 $\frac{1}{2}$ oz. flour
1 oz. butter or margarine	A pinch of salt
	2 eggs

Place the water and fat in a saucepan and bring to the boil. Add the flour and salt to the mixture and beat well over a low heat until it forms a ball. Cool slightly and add the eggs a little at a time, beating well. Using a forcing-bag, force into éclair shapes on to a greased tin. Bake in a moderately hot oven (400° F.) for about 30–40 minutes. Allow to cool slightly, slit down one side, and remove any soft part from the inside. Fill with sweet or savoury filling.

#### Chocolate Eclairs

Synthetic or fresh cream or thick custard	Choux pastry
	Chocolate glacé icing

Make the choux paste, and put into a large forcing bag fitted with a plain  $\frac{1}{2}$ - or  $\frac{1}{4}$ -in. nozzle. Pipe fingers of paste about 3 $\frac{1}{2}$ –4 in. long on to a

greased baking sheet, keeping the éclairs very even in size. Bake in a moderately hot oven (400° F.) for about 30–40 minutes, according to size, until the éclairs are well risen, golden-brown, and very light in texture. Remove them from the tin, slit each down the side to allow the steam to escape, and put on a rack to cool. Fill them with whipped cream, mock cream, or a thick sweet custard, and coat the top of each with a little chocolate glacé icing.

#### Cream Buns

Sweetened cream, or thick custard	Choux pastry
	Icing sugar or chocolate sauce

Make the choux paste and put it into a forcing-bag fitted with a plain  $\frac{1}{2}$ - or  $\frac{1}{4}$ -in. nozzle. Pipe the mixture in rounds on to a greased baking-tin, which should be covered with an inverted meat tin, or into a tin which has a tightly fitting lid. Cover, and bake in a moderately hot oven (400° F.) for 45–50 minutes without opening the tin, as this would cause the steam to escape and the buns to collapse. When they are cooked, remove them carefully, slit to allow the steam to escape and leave them on a rack to cool. Fill them with cream or custard and dredge with icing sugar, or serve with a chocolate sauce.

#### Profiteroles

To make these miniature cream buns, force small balls of choux pastry through a  $\frac{1}{4}$ -in. plain pipe on to a baking-sheet, and bake in a moderately hot oven (400° F.) till well risen, crisp, and golden-brown (20–25 minutes). Split and cool on a rack. Fill with cream, and ice with glacé icing.

#### Flan Pastry

Flan or biscuit crust is a richer, sweetened type of short-crust pastry, suitable for flans and cold lunch or dinner sweets and for tea-time pastries.

#### Basic Recipe

4 oz. flour	1 teaspoonful sugar
A pinch of salt	1 egg yolk
2 oz. fat	Cold water to mix

Sieve the flour and salt into a bowl and rub in the fat (margarine or a mixture of margarine and white fat) using the finger-tips. Add the sugar and mix with the egg-yolk and sufficient cold water to make a stiff dough. Knead slightly till it is quite smooth, then use as required. To line a flan ring: Place a flan ring on greaseproof paper on a baking-tin. Line the flan ring with pastry, without stretching it. Lightly roll across top of flan to trim edge cleanly. Put greaseproof paper in the flan and fill it with baking-beans. (A sandwich tin may be used instead of a flan ring.)

Flans are frequently baked "blind," but the filling is sometimes added first and cooked with the pastry. Flan pastry should be cooked in a hot oven (425° F.); after about 10–15 minutes remove the beans and lower the temperature to finish cooking the pastry a further 5–10 minutes.

#### Mixed Fruit Flans

Bake some pastry flan cases and fill with fresh, tinned, or lightly stewed fruit, drained free of juice. Make a jelly glaze by dissolving 1 teaspoonful of gelatine (or more, according to type) in  $\frac{1}{2}$  pint of the sweetened fruit juice. When just beginning to set, pour it over the fruit.

#### Balmoral Tartlets

6 oz. flan pastry	$\frac{1}{2}$ oz. cake-crumbs
1 oz. margarine	1 oz. glacé cherries and candied peel, mixed
1 oz. castor sugar	
1 egg	$\frac{1}{2}$ oz. cornflour

Line ten to twelve patty tins with the pastry. Cream fat and sugar until light and white, and beat in egg-yolk. Add the crumbs, shredded cherries, and peel and cornflour. Fold in the stiffly beaten egg-white. Put thin strips of pastry over the top, and bake in a moderate oven (375° F.) for 20 minutes.

#### Hot-water Crust Pastry

8 oz. flour	$\frac{1}{2}$ gill hot water or milk
$\frac{1}{2}$ teaspoonful salt	and water
2 oz. lard	

Sieve the flour and salt into a warm basin. Melt the lard in a small saucepan, add the liquid,

and bring just to boiling point. Pour this mixture into the centre of the flour and mix quickly into a paste. Turn out on to a floured board and knead with the hands until smooth and free from cracks. Form into the shape required as quickly as possible, as this pastry hardens on cooling.

### Raised Veal-and-ham Pie

#### For the Filling

12 oz. veal	Pepper and salt
$\frac{1}{2}$ lb. ham	Cold water
Parsley	2 eggs
1 lemon	Some jelly stock

#### For the Pastry

1 lb. flour	$1\frac{1}{2}$ gills water or milk
1 teaspoonful salt	and water
4 oz. lard	Yolk of egg to glaze

*To Prepare the Filling.*—Remove any skin and bones from the meat, wipe with a damp cloth, and cut it in small pieces. Add to it the ham, cut in small pieces, and season with chopped parsley, a little grated lemon rind and juice, pepper, and salt. Mix well together and moisten with a little cold water. Hard-boil the eggs and cut them into six to eight pieces.

*To Make the Pie-crust.*—Make the pastry as directed above. Cut off about a quarter of the quantity and keep it warm for making the lid and decoration later on. Mould the larger piece with the hands into an oval or round pie-case, making it the desired height and with walls and bottom of an equal thickness. At first the pastry may be inclined to collapse, but as it hardens it will stand up and retain its form. Sometimes a jar or tin is put in the centre to help with the moulding.

*To Finish the Pie.*—Fill the case with the meat mixture and eggs, and shape it up again if necessary. Roll out the remaining piece of pastry, wet the inside edge of the pie-crust and lay on the cover. Press the two edges together, and trim round neatly with a pair of scissors, leaving a ridge about  $\frac{1}{2}$  in. in height standing straight up round the pie. Snip this ridge with the scissors at a distance of  $\frac{1}{2}$  in. apart. Then, with the fingers bend the fringe-like pieces outwards and inwards alternately, to make a pretty edge. Make a good hole in the centre of the pie and brush all over with yolk of egg beaten with a little water. Roll out any remaining scraps of pastry and cut out leaves and narrow strips for decoration. Fix these on to the sides and top of the pie and give them also a coating of egg. Pin or clip a double piece of stiff kitchen paper (greased on the inside) round the outside of the pie, to keep it in position. Lift the pie with a fish-slice or broad knife and place it on a greased baking-tin.

Bake in a hot oven (425° F.) for 15–20 minutes, and then in a cooler one for  $1\frac{1}{2}$  hours or longer, until the meat feels quite tender when tested with a skewer and the pastry is golden-brown. Have ready some well-seasoned stock that will jelly when cold: this may be made from the bones and trimmings of the veal, with a little gelatine added if necessary. Fill up the pie with this by means of a filler, and set it aside until cold. Serve with salad.

### Pork Pie

1 lb. lean pork pieces	Pepper and salt
1 apple	$1\frac{1}{2}$ lb. hot-water crust
A pinch of powdered cloves	Egg yolk
	Stock

Wipe the meat and cut into small pieces. Peel, core, and slice the apple and mix it with the meat, together with the cloves and seasoning. Sprinkle with 1 tablespoonful of water. Wash any bones, place them in a pan, cover with cold water, and allow to simmer gently to make stock for the pie.

Make the pastry: cut off one-quarter of the paste and leave it in a warm place. With the remainder line the raised pie mould, or shape it by hand into an oval or round case, then fill up with the prepared meat mixture. Roll the reserved piece of pastry to form a lid. Make a hole to allow the steam to escape, trim the edges, and decorate as desired. Brush the top with egg yolk, and if a mould is not being used, pin a band of greased paper round the pie. Bake in a moderately hot oven (400° F.) for about 1 hour,

then reduce to a moderate heat (350° F.) and cook until the meat feels tender when tested with a skewer. When the pie is cooked fill it up with well-seasoned stock and serve hot or cold.

An economical raised pie can have sausage meat as its main filling. Add some hard-boiled egg, herbs, and a par-boiled onion, all finely chopped. Season well, and fill the pastry case. Bake in a hot oven (425° F.) for about  $\frac{1}{2}$  hour to cook the pastry, then reduce temperature and cook for a further hour.

### Game Pie

$\frac{1}{2}$ lb. veal and	1 blackcock, or other
$\frac{1}{2}$ lb. pork or	game bird
1 lb. sausage-meat	1 lb. hot-water crust
Seasonings	Beaten egg to glaze
1 rasher bacon	Stock

Cut up the meat and mince it finely, mixing it with the seasonings. Cut the bacon into small pieces and the game into small joints, removing the bones. Line a tin or pie mould with pastry and put a layer of minced meat (or sausage-meat) at the bottom and round the sides. Put the game and bacon in the pie and then a layer of meat or sausage-meat. Cover with pastry and decorate. Glaze the top and bake for about 2 hours in a moderately hot oven (400° F.). Add stock.

### PUDDINGS HOT AND COLD

#### Baked Custard (Basic Recipe)

1 pint milk	1 oz. sugar
2 eggs	Nutmeg

Heat the milk, but do not boil it. Beat the eggs and the sugar, then add the hot milk, stirring. Strain into a greased pie-dish and grate a little nutmeg on the top. Bake in a slow oven (350° F.) for about 40 minutes, until the custard is set.

On no account allow the mixture to boil, or the eggs will curdle.

#### Bread-and-butter Pudding

2–3 slices thin bread	$\frac{1}{2}$ oz. sugar
and butter	$\frac{1}{2}$ pint milk
1–2 oz. currants or	1 egg
sultanas	Nutmeg

Cut the bread and butter into neat strips, and lay in a buttered pie-dish, buttered side up, sprinkling each layer with fruit and sugar (but omitting fruit in the top layer). Heat the milk and pour on to the beaten egg. Strain into the pie-dish, grate nutmeg on top, and stand aside for  $\frac{1}{2}$  hour to let the bread swell. Bake in a moderate oven (375° F.) for about  $\frac{1}{2}$  hour, until set and lightly browned.

#### Queen of Puddings

$\frac{1}{2}$ pint milk	$\frac{1}{2}$ oz. sugar
$\frac{1}{2}$ pint breadcrumbs	2 egg yolks
Grated rind of 1 lemon	2 tablespoonfuls rasp-
$\frac{1}{2}$ oz. butter	berry or other jam

#### For the Meringue

2 egg-whites	2 oz. sugar
--------------	-------------

Heat the milk and pour it on to the breadcrumbs; add the lemon rind, butter, and sugar, and leave aside for about  $\frac{1}{2}$  hour for the bread to swell. Beat in the egg-yolk and pour the mixture into a greased pie-dish. Bake in a moderately hot oven (375° F.) for about  $\frac{1}{2}$  hour, until set.

Spread a thick layer of jam on the top, heating the jam if necessary, so that it will spread easily. Whisk the egg-whites very stiffly, then fold in  $1\frac{1}{2}$  oz. ( $1\frac{1}{2}$  tablespoonfuls) of the sugar. Pile on top of the pudding and dredge with the remaining sugar. Return to a moderate oven (350° F.) and leave for 20–30 minutes, until the meringue is lightly coloured and crisp to the touch.

#### Canary Pudding

4 oz. margarine	$\frac{1}{2}$ teaspoonful baking-
4 oz. sugar	powder
2 eggs	A pinch of salt
4 oz. flour	Milk, if necessary

Cream the fat and sugar until light and fluffy. Add the eggs one at a time, beating well after each addition. Sieve the flour, baking-powder, and salt, and fold all into the creamed mixture. Add

milk, if required, to give a dropping consistency. Put the mixture into a greased basin, cover with greaseproof paper, and steam for 1½ hours. Serve with sauce.

#### Variations on Canary Pudding

**Syrup Pudding.**—Put 2 tablespoonfuls golden syrup into the greased basin before adding the pudding mixture.

**Lemon or Orange.**—Add the finely grated rind of 1 lemon or orange after beating in the eggs.

**Chocolate.**—Sieve 1 oz. cocoa into the dry ingredients, and add a little extra liquid to mix.

**Ginger.**—Add 2 oz. chopped preserved ginger to the dry ingredients.

#### Spotted Dick

8 oz. flour	4 oz. finely chopped suet
½ teaspoonful salt	3 oz. sugar
1 teaspoonful baking-powder	4 oz. currants
	Milk to mix

Sieve the flour, salt, and baking-powder. Add the suet, sugar, and cleaned currants. Mix with sufficient milk to make a soft dough. Grease and flour a pudding-cloth, place the dough on the cloth, and tie both ends with a piece of string, leaving enough room for the pudding to swell. Cook in fast-boiling water for 2 hours.

#### Christmas Pudding

6 oz. flour	2-3 fresh eggs
½ teaspoonful mixed spice	A few drops of almond essence
½ teaspoonful grated nutmeg	A few drops of vanilla essence
2 oz. breadcrumbs	1 teaspoonful lemon juice or substitute
4 oz. chopped suet	1 small teaspoonful gravy browning or caramel
1-1½ lbs. mixed dried fruit	Milk or milk and water to mix, with a little brandy if available.
Grated rind of 1 orange	
1 grated carrot or 1 finely chopped apple	
3 oz. sugar	

Sieve the flour and spices into a bowl, and add the breadcrumbs, suet, cleaned and prepared dried fruit, grated orange rind, carrot or apple, and the sugar. Mix with the beaten eggs, essences, lemon juice and gravy browning, adding a little liquid to give a stiff dropping consistency.

If suet is not available, substitute 2 oz. margarine and 2 oz. cooking-fat. This should be rubbed into the flour before the rest of the ingredients are added.

Three-quarters fill one large well-greased basin (or two small ones), cover closely with greased paper or a floured cloth, and steam for 5-6 hours.

When the pudding is cooked, allow the basin and covering to dry thoroughly, then place a clean cloth or greaseproof paper over the original coverings (which will have been sterilised by being boiled with the pudding). If protected in this way the pudding will be ready for further cooking on Christmas Day. Store in a cool, dry place.

#### Basic Batter Recipe

4 oz. flour	1 egg
½ teaspoonful salt	½ pint milk

Sieve the flour and salt into a basin and make a well in the centre. Drop in the egg and half of the milk, and mix in a little of the flour at a time, using a wooden spoon and keeping the mixture smooth, until a thick creamy mixture is obtained. Beat for 5-10 minutes until the mixture is full of bubbles. Stir in the rest of the milk and cover and stand, or use at once.

#### Coating Batter

4 oz. flour	1 egg
½ teaspoonful salt	½ pint milk

Sieve the flour and salt into a basin and make a well in the centre. Drop in the egg and half of the milk, and mix in a little of the flour at a time, using a wooden spoon and keeping the mixture smooth, until a thick, creamy mixture is obtained. Beat for 5-10 minutes until the mixture is full of bubbles. Stir in the rest of the milk and cover and stand, or use at once.

#### Pancakes

Make the batter according to the basic recipe opposite. Warm a small frying-pan, rub with a little salt and kitchen paper and wipe clean. This "tempering" ensures that the pancakes will not stick, and it need be done only at the beginning of the frying.

Melt the cooking-fat in a small pan, pour a little into the prepared frying-pan, and when smoking hot pour it back into the saucepan; a film of fat will be left, which will be sufficient for frying the pancakes.

Pour in slowly just enough batter to cover the bottom of the pan. When set and lightly browned on one side, turn or toss and cook the other side. Turn out on to a sugared paper, dust with castor sugar, sprinkle with lemon juice, and roll up.

#### Apple Fritters

Coating batter	Fat for frying
Cooking-apples	Sugar

Make some coating batter according to the directions. Peel and slice the apples in rings. Dip the apple rings into the coating batter, using a skewer to lift them out. Put them into smoking hot fat. Fry until golden-brown on one side, then turn them over to cook the other side. Drain thoroughly before serving. Quartered bananas and sections of orange, or halved peaches, also make good fruit fritters.

Serve fritters as soon as possible after making, as they soon lose their crispness. They may be rolled in sugar, or accompanied by a sweet sauce.

#### Apple Charlotte

1 lb. apples	1 lemon
3 oz. breadcrumbs	4 oz. sugar
2 oz. grated suet	2 oz. butter

Peel and slice the apples. Mix together the breadcrumbs, suet, grated lemon rind, and sugar. Put a layer of apples in a pie-dish, then a layer of the breadcrumb mixture, add a squeeze of lemon juice and a few pieces of butter. Repeat until the dish is full, finishing with a layer of breadcrumbs and a little butter. Bake in a moderate oven (350° F.) about 1½ hours or until the apples are tender. Serve with custard or cream.

An alternative method is to line the dish with the breadcrumb mixture (reserving a little for the top), fill with the sliced apples and cover with the remaining breadcrumbs, etc. Bake as above.

#### Fruit Jelly

½ pint fruit-squash juice	½-1 oz. gelatine
½ pint hot water	Sugar to taste

Mix the fruit squash with the water. Dissolve the gelatine in ½ pint of the mixture over a gentle heat, add to the remaining liquid and sweeten to taste. Pour into a wetted 1-pint mould and put in a cool place to set. Turn out and decorate with slices of oranges and other fresh fruit, sprinkled with sugar.

#### Milk Jelly

1 pint milk	2 oz. castor sugar
Thinly peeled lemon rind	½-1 oz. gelatine
	A little water

Put the milk, lemon rind, and sugar into a pan, and allow them to infuse over gentle heat for about 10 minutes. Dissolve the gelatine in the water and add the cooled milk. Strain the mixture into a wetted mould and leave to set. Turn out the jelly, dip mould into fairly hot water (allow longer for a china one), free edge of jelly, invert on to the dish, and shake well.

#### Apple Snow

2 sponge cakes	Juice of ½ lemon
½ pint cup custard	1 white of egg
3 oz. sieved stewed apple	Colouring, if liked
3 oz. castor sugar	Cherries, angelica, to decorate

Cut the sponge cakes into thin slices, lay in a glass dish and pour the custard over; allow to soak. Put the apple pulp in a basin and add the sugar and lemon juice. Whisk the white of egg until stiff, add to the apple mixture, add colouring if liked and continue whisking until stiff and very fluffy. Pile on to the custard in the dish and serve at once, decorated with cherries, angelica, etc.

**Honeycomb Mould**

- |                         |  |
|-------------------------|--|
| 2 large eggs            | 1- $\frac{1}{2}$ oz. powdered gelatine |
| 1 pint milk             |  |
| $\frac{1}{4}$ oz. sugar | 2 tablespoonfuls water                 |
| Vanilla essence         |  |

Separate the yolks and whites of the eggs. Make a custard with the yolks, milk, and sugar, and flavour with vanilla. Dissolve the gelatine in the water, and add it to the custard. Whisk the egg-whites very stiffly and fold lightly into the cool custard mixture. Pour into a glass dish or mould and turn out when set.

**Charlotte Russe**

- |  |   |
|--|---|
| $\frac{1}{2}$ pint lemon jelly           | 2 tablespoonfuls milk                           |
| Cherries and pistachio nuts, or angelica | $\frac{1}{2}$ pint cream                        |
| 8-10 Savoy fingers                       | 1 tablespoonful brandy                          |
| $\frac{1}{2}$ oz. gelatine               | or 1- $\frac{1}{2}$ teaspoonful vanilla essence |
| 2 tablespoonfuls water                   | 1 $\frac{1}{2}$ oz. castor sugar                |

Pour a thin layer of jelly into the bottom of a plain 1-pint soufflé tin and allow to set. Decorate with cherries and pistachio nuts, pour over a thin layer of jelly and allow to set. Line the sides of the mould with Savoy finger biscuits, trimming them at the sides and ends and dipping the ends in the jelly, before putting them into position. Allow to set. Pour in a thin layer of jelly. Dissolve the gelatine in the water over gentle heat and add the milk. Whip the cream until fairly stiff, stir in the gelatine, flavouring, and sugar. Put into the prepared mould and allow to set. When quite set turn out carefully on to a glass or silver dish.

**Summer Pudding**

- |                                    |                                |
|------------------------------------|--------------------------------|
| 2 tablespoonfuls water             | 4 oz. bread                    |
| 4 oz. sugar                        | Whipped cream or custard sauce |
| 1 lb. raspberries and red-currants |                                |

Put the water and sugar together and bring to the boil, add the fruit and stew carefully, until tender. Line a pudding-basin with thin slices of bread, pour in the stewed fruit, and cover with thin slices of bread; the basin should be full. Place a saucer with a weight on it on top of the pudding. Leave for several hours. Turn out and serve with whipped cream or cold custard sauce.

**Chocolate Soufflé**

- |                            |   |
|----------------------------|---|
| 1 oz. almonds              | 2 tablespoonfuls water                      |
| 2 oz. chocolate            | Vanilla essence                             |
| $\frac{1}{2}$ pint milk    | $\frac{1}{2}$ pint cream or evaporated milk |
| 3 eggs                     | Pistachio nuts                              |
| 2 oz. castor sugar         | Whipped cream                               |
| $\frac{1}{2}$ oz. gelatine |   |

Prepare a soufflé case. Blanch the almonds, shred them, and brown lightly in the oven. Dissolve the chocolate in the milk, whisk the egg-yolks, sugar and dissolved chocolate over a pan of very hot water until thick and creamy, then remove from the heat. Dissolve the gelatine in water then stir into the whisked mixture, together with the chopped almonds and vanilla essence. Fold in the whipped cream lightly. Whip up the whites of egg very stiffly and fold them into the mixture. Pour into the prepared soufflé case and leave to set. Before serving, decorate with pistachio nuts and whipped, sweetened, and flavoured cream.

**Note:** To prepare soufflé case cut a strip of firm paper long enough to go round the soufflé case, overlapping slightly and deep enough to come about 2 in. above the rim of the case. Tie firmly round the case with string.

**Lemon Mousse**

- |                        |                            |
|------------------------|----------------------------|
| 2 tablespoonfuls sugar | $\frac{1}{2}$ oz. gelatine |
| 1 large lemon          | 2 tablespoonfuls water     |
| 3 eggs                 | Cream                      |

Prepare a soufflé case. Add the sugar and the grated rind of  $\frac{1}{2}$  lemon to the egg-yolks and beat until light and creamy. Add the strained lemon juice. Dissolve the gelatine in the water over gentle heat and add it to the egg mixture. Beat until the mixture is well incorporated. Fold in the stiffly beaten whites of egg. Pour the mixture into the prepared case and leave to set. Decorate with whipped, sweetened, and flavoured cream.

**Vanilla Ice**

(Using gelatine)

- |   |   |
|---|---|
| 1 teaspoonful custard powder or cornflour | A few drops of vanilla essence                                |
| $\frac{1}{2}$ pint milk                   | 1 teaspoonful gelatine dissolved in 2 tablespoonfuls of water |
| 1 egg                                     |   |
| 1 tablespoonful sugar (approx.)           |   |

Blend the custard powder or cornflour with a little of the milk. Bring the rest of the milk to the boil and pour on to the blended mixture, stirring well. Return to the saucepan, bring to the boil, and boil for a minute or two, stirring. Remove from the heat, add the beaten egg, and cook gently for a further minute or so, still stirring. Remove from the heat and add the sugar and vanilla essence to taste.

Dissolve the gelatine in the water over gentle heat, and when it is quite dissolved stir it into the custard mixture. Allow to cool, beating or whisking at intervals to prevent a skin forming and to aerate the mixture. Freeze in the usual way.

**BREAD AND ROLLS**

The processes in bread-making should be followed carefully, bearing in mind that yeast requires a warm temperature in which to live. Only sufficient yeast should be bought for immediate use, as it will only keep a day or two. Dried yeast can, however, be kept in a tin for about six months. The following processes are the basis of all yeast cookery:

**Warming.**—Warm the bowl of flour and liquid (water, or milk and water). The temperature of the liquid should be lukewarm or blood heat (98° F.).

**Creaming the Yeast.**—Add  $\frac{1}{2}$  teaspoonful of sugar to the yeast for creaming.

**Adding the Fat.**—Incorporate the fat into the flour, either by rubbing it in or by adding it in melted form.

**Setting the Sponge.**—Pour the mixture of yeast and water into a well in the flour, and leave to set the sponge for 10-15 minutes.

**Mixing the Dough.**—Mix the dough to obtain a soft elastic and almost sticky mixture, allowing about  $\frac{1}{2}$  pint liquid to 1 lb. flour.

**Kneading.**—Unless kneading is thorough, the bread will be full of holes. Turn the dough on to a floured board and knead by lifting the edge of the dough, and bringing it to the centre.

**Rising.**—Leave the dough in a bowl covered with a damp cloth in a warm place to rise. It should be left until it has doubled its size.

**Shaping.**—Knead the dough for another 8 minutes and cut into required shapes, allowing the tins to be three-parts filled.

**Proving.**—Put the prepared loaves or rolls in the tins and leave in a warm place for 10-20 minutes to prove.

**Baking.**—Put the loaves in a hot oven for about 15 minutes, to kill the yeast, and then lower the heat to finish cooking. Allow  $\frac{1}{2}$  hour for a 2-lb. loaf. To test tap the underside of the loaf, and if a hollow sound results the bread is cooked. Leave to cool on a wire tray.

**Basic Bread Recipe**

- |                           |                                   |
|---------------------------|-----------------------------------|
| 3 $\frac{1}{2}$ lb. flour | 1 teaspoonful sugar               |
| $\frac{1}{2}$ oz. salt    | 1 $\frac{1}{2}$ pints tepid water |
| 1 oz. yeast               | (approx.)                         |

Follow the method shown above.

**Brown Bread**

- |                                   |                                |
|-----------------------------------|--------------------------------|
| 10 oz. white flour                | $\frac{1}{2}$ oz. yeast        |
| 1 $\frac{1}{2}$ teaspoonfuls salt | $\frac{1}{2}$ pint tepid water |
| 10 oz. wholemeal                  |                                |

Sieve the flour and salt into a warm bowl and add the wholemeal. Cream the yeast and add the tepid water. Strain into the flour, mix, and knead thoroughly till smooth. Set to rise for 1 hour, then knead slightly. Form into two loaves, put into warm floured tins, and set to prove for 15 minutes. Bake in a hot oven (450° F.) for about 45 minutes, until the bread feels light and is crisp outside.

## Milk Rolls

1 lb. flour	About $\frac{1}{2}$ pint milk and
Salt	water
2 oz. lard	A little beaten egg to
$\frac{1}{2}$ oz. yeast	glaze

Warm the flour, add about  $\frac{1}{2}$  teaspoonful of salt, and rub in the lard. Cream the yeast and add most of the liquid, then add this to the flour and mix to an elastic dough. Knead well. Put to rise for 1 hour, or until double the size. Turn on to a floured board and knead well. Shape into rolls, dinner buns, or twists. Put on to a warmed, greased tin and prove for 10-20 minutes, until they have risen well, but avoid overproving. Bake in a hot oven (450° F.) for 15-30 minutes, according to size. Glaze with beaten egg.

## Chelsea Buns

8 oz. flour	$\frac{1}{2}$ gill warm milk and
A pinch of salt	water
3-4 oz. currants and	1 oz. margarine or lard
sultanas	1 egg
2 oz. sugar	A little melted fat
$\frac{1}{2}$ oz. yeast	2 teaspoonfuls sugar to
	glaze

Sieve together the flour and salt and put to warm. Clean the currants and sultanas and mix with 2 teaspoonfuls of the sugar. Cream the yeast with  $\frac{1}{2}$  teaspoonful of sugar and add it to the liquid. Add this to one-third of the flour and set it to sponge. Rub the fat into the remaining flour, add the rest of the sugar, and gradually beat in the egg. Next mix in the sponged mixture. Beat all thoroughly with the hand and put in a warm place to rise. When it has doubled its size knead lightly on a floured board and then roll into an oblong strip. Brush over with melted fat and sprinkle evenly over it the mixed fruit and sugar. Roll up and cut into twelve even-sized slices. Pack lightly, cut side down, into a greased tin, which should have straight sides, (e.g., A Yorkshire pudding-tin). Allow to prove for 15 minutes, then bake in a hot oven (450° F.) for 15-20 minutes. Glaze with sugar and water.

## Doughnuts

8 oz. flour	Castor sugar
A pinch of salt	1 egg
2 oz. margarine	Jam
$\frac{1}{2}$ oz. yeast	Fat for frying
3-4 tablespoonfuls	Ground cinnamon (op-
warm milk	tional)

Warm the sieved flour and salt in a basin and rub in the margarine. Cream the yeast with 1 teaspoonful castor sugar and add to it the milk and beaten egg. Pour into the centre of the flour and mix to a soft dough. Beat well with a wooden spoon or the hand, and leave to rise until the dough becomes twice the original size; then knead lightly. Divide into ten to twelve pieces. Shape each into a ball, flatten a little, and place about  $\frac{1}{2}$  teaspoonful of jam in the centre of each piece. Gather the edges together over the jam, forming balls. Place on a greased and floured tin and leave in a warm place for a few minutes to prove. Heat some deep fat until smoking faintly but not too hot, and fry the doughnuts in it until golden-brown and cooked through (about 5 minutes). Drain, then turn out on to a paper and dredge with castor sugar. If preferred, sprinkle with a little ground cinnamon mixed with sugar. Serve very fresh.

## Crumpets

$\frac{1}{2}$ oz. yeast	A pinch of bicarbonate
1 pint milk and water	of soda
1 lb. flour	1 teaspoonful salt

Cream the yeast with a little of the tepid liquid, add the rest and pour it into the flour. Beat very thoroughly with the hand for 5 minutes. Cover the bowl and stand it in a warm place for 1 hour. Dissolve the bicarbonate of soda and salt in a little warm water and add it to the sponge mixture. Beat it up, and put it to rise again for  $\frac{1}{2}$  hour. Have ready a greased girdle, moderately hot; grease some crumpet rings and let them heat on the girdle. Pour in enough batter to cover the bottom completely and allow it to cook gently until the top is set. Remove the rings, turn the crumpets over, and allow them to dry for a few minutes on the underside.

## Sally Lunn Tea-cakes

12 oz. flour	1 egg
$\frac{1}{2}$ teaspoonful salt	1 oz. lard or margarine
$\frac{1}{2}$ oz. yeast	Egg or milk and sugar
1 teaspoonful sugar	to glaze
$\frac{1}{2}$ pint milk and water	

Sieve the flour and salt into a basin. Cream the yeast with the sugar, stir in the tepid liquid, and pour the mixture into the centre of the flour. Add the beaten egg and melted fat, mix to a light, soft dough, and knead well. Divide into two or three pieces, shape into rounds, and put into small greased and floured cake-tins, half-filling them. Set in a warm place until the dough rises to the top of the tins, then bake in a hot oven (450° F.) for 15-20 minutes. A few minutes before they are ready to be taken out of the oven, brush the tea-cakes over with a little beaten egg, or with milk and sugar.

## Rum Baba

8 oz. flour	4 oz. margarine
$\frac{1}{2}$ teaspoonful salt	4 oz. currants, candied
$\frac{1}{2}$ oz. yeast	peel and chopped nuts
$\frac{1}{2}$ teaspoonful sugar	Hot rum syrup
$\frac{1}{2}$ pint warm milk	Mock cream and glacé
4 eggs	fruits (optional)

Sieve the flour and salt into a bowl. Cream the yeast and sugar and add the warm milk. Pour the mixture into the centre of the dry ingredients and sprinkle flour on top. Put in a warm place to work for about  $\frac{1}{2}$  hour. Beat the eggs and add them with the melted fat to the mixture, beating well with the hand. Brush a large border mould or some small ones with melted fat, and put in the currants and chopped peel and nuts. Half-fill the moulds with the yeast mixture, cover, and put in a warm place until the mixture rises to the top of the tins. Bake in a moderate oven (375° F.) for about  $\frac{1}{2}$  hour, then turn out and prick the surface. Pour over some rum syrup (made by heating 4 oz. sugar with  $\frac{1}{2}$  pint water, a squeeze of lemon juice, and rum to taste) and serve hot; or decorate with mock cream and glacé fruits and serve cold.

## Croissants

1 $\frac{1}{2}$ lb. flour	$\frac{1}{2}$ pint milk and water
$\frac{1}{2}$ oz. salt	1 oz. yeast
6 oz. margarine	$\frac{1}{2}$ oz. sugar

Warm the flour and add the salt. Melt  $\frac{1}{2}$  oz. of the fat, add it to the liquid, and warm. Cream the yeast and sugar. Make a well in the centre of the flour and mix to a light dough with the yeast and liquid. Knead lightly and set to rise for about  $\frac{1}{2}$  hour. Knead lightly on a floured board and roll out to an oblong. Place one-third of the remaining fat in small heaps on the top two-thirds of the dough, then fold in three, turning the bottom third up and bringing the top third over it. Seal the ends with the rolling-pin and give one half-turn. Roll again into an oblong, and repeat with the two remaining portions of margarine. Roll out dough very thinly and cut into squares and then triangles, finishing with the point, and curling the ends round to form a crescent. Prove for about 10 minutes on a greased tin. Then brush over gently with beaten egg and milk, and bake in a hot oven (450° F.) for 10-15 minutes.

**Scones.**—A plain scone mixture can have different additions which add to the variety of this simply made dish. Scones may be cooked in the oven or on a girdle.

## Oven Scones

8 oz. flour	$\frac{1}{2}$ teaspoonful bicar-
$\frac{1}{2}$ teaspoonful salt	bonate of soda
1 teaspoonful cream of	1-2 oz. fat
tartar ( $\frac{1}{2}$ teaspoonful,	$\frac{1}{2}$ pint (approx.) fresh or
if sour milk is used)	sour milk

Sieve the flour, salt, cream of tartar, and bicarbonate of soda into a basin and rub in the fat. Make a well in the centre and stir in enough milk to give a light, spongy dough just firm enough to handle. Turn it on to a floured board, knead very lightly if necessary, to remove any cracks; then roll out lightly to 1 in. thick, or pat it out with the hand. Cut rounds with a sharp cutter,

dipped in flour, or cut it into triangles with a sharp knife. Place on a floured baking-sheet, glaze if desired with beaten egg or milk, and bake near the top of a hot oven (450° F.) for 7-10 minutes till brown and well risen. Cool on a rack.

*Fruit Scones.*—Add 2 oz. currants, sultanas, raisins, or chopped dates to dry ingredients.

*Oatmeal Scones.*—Follow the same recipe, substituting 2 oz. oatmeal for 2 oz. of the flour.

*Rich Afternoon Tea Scones.*—Follow the same recipe, adding 1-2 tablespoonfuls castor sugar to the dry ingredients, and using 1 beaten egg with 1-2 tablespoonfuls water or milk to mix. If desired, 2 oz. dried fruit may be included, rather less sugar being used.

#### Plain Girdle Scones

8 oz. flour 1½ oz. butter or margarine  
½ teaspoonful bicarbonate of soda ½-1 oz. sugar  
1 teaspoonful cream of tartar ½ pint milk or milk and water  
A pinch of salt

Sieve the dry ingredients, rub in the fat, and add the sugar. Mix to a fairly soft dough with the liquid, then turn it on to a floured board and knead it very lightly. If necessary, to remove any cracks. Roll out ½ in. thick, cut in triangles or rounds, and place on a hot, floured girdle. Cook steadily until well risen and pale brown underneath, turn over gently and cook until the other side is browned and the centre is dry. (If desired, 2 oz. sultanas may be included: add them with the sugar.)

#### Drop Scones

8 oz. flour 1-3 oz. sugar  
½ teaspoonful bicarbonate of soda 2 eggs  
½ teaspoonful cream of tartar ½ pint sour milk or buttermilk

Sieve the flour and raising agents, add sugar, mix with eggs and milk to a fairly thick batter. Place spoonfuls of mixture on the hot, greased girdle; keep at a steady heat, and turn scones when the bubbles burst. Cook the scones till golden on both sides, and keep them in a cloth to prevent their becoming dry and crisp. Serve them with butter and jam.

#### Potato Cakes

1 lb. potatoes 1 oz. margarine  
1 teaspoonful salt 3-4 oz. flour

Boil, drain, and sieve the potatoes. Add salt and margarine, and work in flour. Knead the dough lightly on a floured board, roll to about ½ in. thick, and cut into triangles. Cook on a hot, greased girdle till brown on both sides. Serve hot with butter.

### BISCUITS

Biscuits are made from a pastry-like dough, and during the mixing it is therefore essential to add the liquid slowly to avoid a sticky dough which may be difficult to manage. Roll the biscuit dough out on a floured board and prick the surface of the dough to prevent rising. Bake on the top shelf of a moderately hot oven (350-400° F.). Biscuits require watching during baking, as they cook quickly. Remove from the tray as soon as they are done, and cool on a wire tray. Biscuits should be stored in an airtight tin.

#### Digestive Biscuits

6 oz. flour 1 teaspoonful baking-powder  
1 teaspoonful salt 3 oz. lard or cooking-fat  
1½ oz. coarse oatmeal 3 oz. lard or cooking-fat  
½-1 oz. sugar Milk to mix

Mix the dry ingredients together and rub in the fat very thoroughly with the finger-tips. Mix in enough milk to give a firm dough. Turn it on to a floured board, knead it lightly, and roll out rather thinly, then cut it in rounds. Place the biscuits on a greased baking-sheet, prick them well, and bake in a moderately hot oven (400° F.) until they are lightly coloured—about 15 minutes.

FF (65th Ed.)

### Easter Biscuits

12 oz. flour 1 oz. peel  
Pinch of salt Pinch of saffron steeped overnight in a table-spoonful of milk or brandy  
6 oz. butter or margarine  
5 oz. castor sugar White of egg  
1 egg Little castor sugar  
3 oz. currants

Sieve the flour and salt. Cream the butter and sugar. Add the beaten egg to the creamed mixture with a little of the sieved flour. Stir in remaining flour, currants, and finely chopped peel, and mix in the saffron-flavoured milk or brandy. The dough should be softer than pastry but stiff enough to roll out.

Roll out ½ in. thick and cut into large rounds. Place on a greased baking-sheet and bake in a moderately hot oven (400° F.) for about 20 minutes, until lightly coloured.

After 10 minutes' baking brush with beaten white of egg and dredge with castor sugar.

#### Shrewsbury Biscuits

3 oz. margarine 8 oz. self-raising flour  
3 oz. sugar 1 tablespoonful water  
½ an egg (approx.)  
Vanilla essence

Put the fat and sugar in a bowl and cream together until soft and white, then gradually add the egg and a few drops of vanilla essence (or a little grated lemon rind), and work in the flour, together with enough water to form a soft, pliable dough. Roll out to about ½ in. in thickness and cut into fancy shapes with biscuit cutters. Bake in a moderate oven (375° F.) for 15-20 minutes. Cool on a wire tray.

#### Shortbread

6 oz. flour 4 oz. butter (or margarine)  
A pinch of salt 2 oz. castor sugar

Sieve the flour and salt, and rub in the fat. Add sugar, and then knead the mixture until it will bind together. Roll it out on a lightly floured board and form it into a round cake. Crimp edges, prick, and mark into wedges. Put on a tin lined with greased paper, and bake in a moderate oven (325° F.) for 1 hour, or until lightly brown. Cool and dust with sugar.

#### Ginger Biscuits

2 oz. margarine 1 teaspoonful ground ginger  
2 oz. castor sugar 2½ oz. self-raising flour  
1 egg-yolk Wheat flakes

Cream together the fat and sugar and beat in the egg-yolk. Stir in the sieved ginger and flour a little at a time, and knead lightly to form a dough. Form into balls, toss these in wheat flakes, and put on a greased baking-tin. Bake in a moderate oven (375° F.) for about 20 minutes.

#### Chocolate Biscuits

6 oz. self-raising flour 4 oz. castor sugar  
2 tablespoonfuls cocoa A little water  
4 oz. butter or margarine Vanilla essence

Sieve together the flour and cocoa and rub in the fat very thoroughly until the mixture resembles fine breadcrumbs. Add the castor sugar and mix well. Mix to a very firm dough with a tablespoonful or so of cold water to which 1 or 2 drops of vanilla essence have been added. Turn on to a floured board, roll out ½ in. thick, and stamp into rounds or fancy shapes. Put on a greased baking-sheet and cook in a moderately hot oven (400° F.) for about 10-15 minutes.

To finish, dust with castor sugar. As an alternative, make the biscuits thinner, then sandwich together with chocolate butter icing, and ice with chocolate (or white) glacé icing.

#### Brandy Snaps

3 oz. syrup ½ teaspoonful ground ginger or grated lemon rind  
2 oz. sugar 1 teaspoonful brandy (optional)  
3 oz. butter  
2 oz. flour

Melt the syrup, sugar, and butter and allow to cool slightly, then add the flour and ground

ginger or grated lemon rind, mixing well. Stir in the brandy and put in small teaspoonfuls, 3-4 in. apart on a well-greased tin. Bake in a moderate oven (350° F.) until well spread and just golden-brown. Allow to cool for a moment, then lift off with a palette knife and quickly roll over the greased handle of a wooden spoon. Slip off carefully. If the biscuits cool too much, and are too brittle to roll, return them to the oven for a moment to soften.

### Macaroons

2 whites of eggs	1 oz. ground rice (good measure)
4 oz. ground almonds	1 teaspoonful orange flower water
8 oz. castor sugar	

### To Decorate

Split almonds      Little white of egg

Whisk the whites of eggs fairly stiffly. Stir in the almonds, sugar, ground rice, and flavouring, and mix thoroughly. Cover a greased baking-sheet with rice paper and place the mixture in small heaps on the rice paper; or pipe, using a calico forcing-bag and large plain pipe, leaving room for spreading. Place a split almond on each biscuit, brush with white of egg and bake in a moderate oven (350° F.) for about 20-25 minutes until pale golden-brown. It is important to cook macaroons rather slowly, to allow them to colour evenly and to get a good texture.

### Coconut Pyramids or Cones

2 egg-whites	5 oz. desiccated coconut
5 oz. sugar	

Whisk egg-whites stiffly and fold in sugar and coconut. Pile on a greased tin (covered with rice paper if available), press into shape, and bake in a cool oven (275-325° F.) until pale fawn—about ½-1 hour. If desired, tint mixture pink or green before shaping.

### CAKES

Basically there are four different types of cake. Those made by the "rubbing-in" method, by which the fat is rubbed into the dry ingredients and the liquid is added afterwards. These are usually of the plainer variety. Richer cakes are made by creaming the fat and sugar together, adding the eggs to this mixture, and finally the flour. The third method is used for fatless sponges, where the eggs and sugar are whisked together over hot water and the flour is folded into the whisked mixture. For gingerbreads the melted fat and sugar are added to the dry ingredients.

The following rules of cake-making should be observed:

Prepare the tin by greasing with lard or clarified fat. For richer cakes and some whisked sponges line the tin with greased greaseproof paper. Collect and weigh the ingredients carefully, cream the fat and sugar very thoroughly until the mixture has a white fluffy appearance.

Avoid opening the oven door during the cooking. To test the cake to see if it is cooked, press the centre top lightly. It should be spongy and give only lightly to the pressure.

Allow the cake to cool slightly before turning it out of the tin.

Store in a tightly covered tin.

### PLAIN CAKES

#### Rock Cakes

12 oz. self-raising flour	6 oz. margarine
A pinch of salt	6 oz. sugar
½ teaspoonful grated nutmeg	3 oz. currants
½ teaspoonful mixed spice	1½ oz. chopped peel
	1 egg
	Milk to mix

Sieve the flour, salt, and spices. Rub in the fat, and add the sugar, fruit, and peel. Mix with beaten egg and just enough milk to bind. Using a teaspoon and a fork, place mixture in rocky heaps on a greased baking-sheet and bake in a hot oven (450° F.) for 15-20 minutes.

### Plain Fruit Cake

8 oz. self-raising flour	2 oz. sultanas
A pinch of salt	1 oz. desiccated coconut (optional)
3 oz. margarine	
3 oz. sugar	2 eggs
2 oz. currants	Milk to mix

Sieve the flour and salt into a bowl, rub in the fat, and add the sugar. Add cleaned fruit and coconut (if used). Beat the eggs lightly and add them, with a little cold milk. The mixture should now be of a dropping consistency. Put it into a greased tin and bake in a moderate oven (350° F.) for about 1 hour. Leave for a minute or two, then turn out carefully. Place on a wire cake rack to cool.

### Soda Cake

8 oz. flour	Grated nutmeg
A pinch of salt	5 oz. margarine
½ teaspoonful bicarbonate of soda	5 oz. sugar
½ teaspoonful cream of tartar	6 oz. currants
	1 egg
	Sour milk to mix

Sieve the dry ingredients, rub in fat, and add sugar and fruit. Mix with beaten egg and sour milk to a dropping consistency. Put into a 6-in. cake-tin and bake in a moderate oven (375° F.) for about 1 hour.

Note: If no sour milk is available, add 1 teaspoonful lemon juice or a few drops of vinegar to ½ pint fresh milk.

### Dripping Cake

8 oz. self-raising flour	3 oz. dripping
½ teaspoonful mixed spice	5 oz. brown sugar
A little grated nutmeg	8 oz. mixed dried fruits
A pinch of salt	1 egg
	Milk to mix

Sieve the dry ingredients and rub in fat. Add sugar and fruit, mix with egg and milk to give soft dropping consistency. Put in prepared 6-in. tin and bake in moderate oven (375° F.) for 1-1½ hours.

### Plain Chocolate Cake

5 oz. self-raising flour	3 oz. sugar
A pinch of salt	Milk to mix
1 oz. cocoa	Vanilla essence
3 oz. margarine	

Sieve the flour, salt, and cocoa together, and rub in the margarine. Add the sugar and mix with milk and a few drops of vanilla essence to a soft consistency. Put into a prepared 5- or 6-in. cake-tin and bake in a moderate oven (375° F.) for about 40 minutes.

### RICH CAKES

#### Queen Cakes

4 oz. butter or margarine	½ teaspoonful baking powder
4 oz. sugar	A little milk if necessary
2 eggs	2 oz. sultanas
4 oz. flour	

Thoroughly cream the fat and sugar and add the eggs a little at a time, beating well. Fold the sieved flour and baking-powder into the mixture, together with a little milk if necessary, to give a soft dropping consistency. Add the prepared fruit, and place in spoonfuls in greased patty tins. Bake them in a moderately hot oven (400° F.) for 15-20 minutes, until firm to the touch and golden-brown in colour.

### Walnut Layer Cake

6 oz. butter or margarine	2 teaspoonfuls coffee essence
6 oz. sugar	A little milk
3 eggs	Coffee walnut butter cream
6 oz. flour	American frosting
½ teaspoonful baking-powder	Walnuts to decorate

Cream fat and sugar and beat in eggs one at a time. Fold in sieved flour and baking-powder and add essence, with a little milk if necessary to give a soft consistency. Put into three prepared sandwich-tins, and bake in a moderate oven (375° F.) for 35-40 minutes, then cool. Sandwich the cakes together with coffee walnut butter cream, coat with white American frosting, and decorate with halved walnuts before the frosting sets firmly.

## Rich Chocolate Cake

- |                      |                         |
|----------------------|-------------------------|
| 4 oz. butter or mar- | 1½ oz. cocoa            |
| garine               | 1½ teaspoonfuls baking- |
| 6 oz. castor sugar   | powder                  |
| 2 eggs               | A pinch of salt         |
| Vanilla essence      | About ½ pint milk       |
| 8 oz. flour          |                         |

Cream together the fat and sugar, and beat in the eggs and a few drops of vanilla essence. Sieve the flour, cocoa, baking-powder, and salt, and add to the mixture, together with enough milk to give a soft dropping consistency. Put into a prepared 7-in. tin and bake for 1-1½ hours in a moderate oven (375° F.). When the cake is cool, it may either be dredged with icing-sugar or coated with white glacé icing and decorated with chocolate butter cream, piped in an attractive design.

## Madeira Cake

- |                        |                      |
|------------------------|----------------------|
| 8 oz. flour            | 5 oz. butter or mar- |
| A pinch of salt        | garine               |
| 1 teaspoonful baking-  | 3 eggs               |
| powder                 | Milk to mix          |
| A little finely grated | A few drops of lemon |
| lemon rind             | essence              |
| 5 oz. sugar            | Citron peel          |

Sieve dry ingredients, add rind, cream sugar and fat together until light and fluffy, then beat in the eggs a little at a time. Add the sieved dry ingredients to the creamed mixture, alternately with a little milk and the essence. Put in prepared tin and lightly add slices of peel (or put on top as soon as cake sets). Bake 1-1½ hours in moderate oven (350° F.).

## Cherry Cake

- |                       |                      |
|-----------------------|----------------------|
| 8 oz. flour           | 6 oz. butter or mar- |
| ½ teaspoonful salt    | garine               |
| ½ teaspoonful baking- | 6 oz. sugar          |
| powder                | 2 eggs               |
| 3 oz. glacé cherries  | Vanilla essence      |
|                       | Milk to mix          |

Sieve the flour, salt, and baking-powder, and add the glacé cherries, cut into quarters. Cream together the fat and sugar, and beat in the eggs one at a time; add a few drops of vanilla essence. Add the dry ingredients, and mix lightly with a little milk. Put into a prepared tin and bake in a moderate oven (350° F.) for about 1 hour.

If desired, before baking the cake put a few halved cherries on top of it, and sprinkle with castor sugar, to give a crisp, sugary surface.

## Dundee Cake

- |                        |                           |
|------------------------|---------------------------|
| 6 oz. sultanas         | ½ teaspoonful baking-     |
| 3 oz. currants         | powder                    |
| 3 oz. candied peel     | 6 oz. butter or margarine |
| 3 oz. blanched almonds | 6 oz. sugar               |
| 9 oz. flour            | 3 eggs                    |
| ½ teaspoonful salt     | Milk to mix               |

Prepare the fruit and slice the peel finely. Chop the almonds, reserving about ½ oz. for the top of the cake.

Sieve together the flour, salt, and baking-powder. Cream together the fat and sugar, and beat in the eggs one at a time. Add the dry ingredients, and mix with a little milk, if required, to give a stiff dropping consistency. Put the mixture into a prepared 8-in. tin and place the halved, blanched almonds on top. Bake in a moderate oven (350° F.) for 1½-2 hours, until firm to the touch.

## Rich Fruit Cake

- |                       |                        |
|-----------------------|------------------------|
| 1 lb. currants        | 6-8 eggs               |
| 8 oz. raisins         | 12 oz. flour           |
| 1 lb. sultanas        | A pinch of salt        |
| 6 oz. mixed peel      | 2 teaspoonfuls mixed   |
| 4 oz. glacé cherries  | spice                  |
| 4 oz. shelled almonds | Grated rind of 1 lemon |
| 10 oz. margarine      | Lemon juice            |
| 10 oz. castor sugar   | A little milk          |

Clean fruit and chop peel and cherries. Blanch and chop almonds. Have all other ingredients ready. Warm margarine slightly, if hard, but do not over-heat. Cream with sugar until soft and light. Break the eggs separately into a basin, beat lightly, and add one by one to creamed mixture. Beat each egg in very thoroughly

before adding next. The mixture should be light and fluffy. Sieve dry ingredients into a bowl, add fruit and rind. Fold gradually into creamed mixture. Continue to mix in dry ingredients lightly, adding a squeeze of lemon juice and a little milk. Put the mixture, which should be of a stiff dropping consistency, into a lined 9-in. tin. Bake the cake for 4½-5 hours in all, first at 350° F. for about 2 hours, and then at 300° F. Decorate if required.

## SPONGE CAKES

## Sponge Cake

- |                    |             |
|--------------------|-------------|
| 4 eggs             | 4 oz. flour |
| 6 oz. castor sugar |             |

Put the eggs and sugar in a large basin, stand this over a pan of hot water, and whisk the contents very briskly, until light and fluffy—the mixture should be stiff enough to retain the impression of the whisk for a few seconds. Remove from the heat. Sieve one-third of the flour over the mixture and fold in very lightly, using a metal spoon. Add remaining flour in the same way. Pour mixture into a 7-in. cake-tin, greased and dusted with sugar and flour. Bake in a moderate oven (350° F.) for about 1 hour.

## Jam Swiss Roll

- |             |                     |
|-------------|---------------------|
| 3 eggs      | 1 tablespoonful hot |
| 4 oz. sugar | water               |
| 4 oz. flour | Castor sugar        |
|             | Warmed jam          |

Put eggs and sugar in a large basin and stand this over hot water. Whisk the mixture as in recipe above. Sieve one-third of flour over surface of mixture and fold in very lightly, using a metal spoon. Add rest of flour in same way, and stir in hot water. Pour mixture into prepared Swiss roll tin, tipping to allow it to spread over surface; bake in a hot oven (425° F.) for 7-9 minutes, until golden-brown and well risen. When the sponge cake is cooked, turn it out on to paper which has been liberally sprinkled with castor sugar. Remove the paper from the cake. Using a sharp knife, quickly trim off the crisp outer edges of the cake. Spread with warmed jam, make a cut almost through the sponge 1 in. from near edge, and begin to roll. Now roll the sponge as tightly as possible, using the paper to help manipulate it. Put the roll on a wire cake-rack and leave it until cold.

## Genoise Sponge

- |                      |                 |
|----------------------|-----------------|
| 3 oz. butter or mar- | ½ oz. cornflour |
| garine               | 3 large eggs    |
| 2½ oz. flour         | 4 oz. sugar     |

Clarify the butter and sieve the flour and cornflour. Put the eggs and sugar into a large basin, stand it over a saucepan of hot water and whisk briskly until the mixture is light and thick, and stiff enough to retain the impression of the whisk for a few seconds. Remove the basin from the heat. Sift about half of the flour over the surface of the mixture, and fold in very lightly. Add the remaining flour in the same way, alternately with the cooled clarified butter. Pour into a shallow greased and lined tin. Bake in a moderate oven (375° F.) until golden-brown and firm to the touch, the time depending on the depth of the cake—about ½ hour.

Note: Genoise sponge must be very lightly mixed, or the fat will sink and cause a heavy cake.

This mixture may be used as a foundation for layer cakes and iced cakes and also for a variety of iced and decorated petits fours, etc.

## GINGERBREADS

## Gingerbread

- |                        |                        |
|------------------------|------------------------|
| 1 lb. flour            | ½ teaspoonful salt     |
| 1½ teaspoonfuls ground | 8 oz. brown sugar      |
| ginger                 | 6 oz. butter           |
| 2 teaspoonfuls baking- | ½ lb. treacle or syrup |
| powder                 | ½ pint milk            |
| ½ teaspoonful bicarb-  | 1 egg                  |
| onate of soda          |                        |

Sieve dry ingredients. Warm sugar, butter, and treacle, without over-heating. Warm milk and beat egg. Combine all ingredients, mixing very thoroughly. Pour into a greased and lined tin and bake in a moderate oven (350° F.) for about 1½ hours, or until the centre is firm to the touch.

## Parkin

8 oz. flour	A pinch of salt
8 oz. medium oatmeal	$\frac{1}{2}$ teaspoonful bicarb.
2 teaspoonfuls ground ginger	onate of soda
$\frac{1}{2}$ teaspoonful mixed spice	4 oz. dripping
	8 oz. treacle
	4 oz. brown sugar

Sieve the dry ingredients into a bowl and mix well. Melt the dripping, treacle, and sugar in a saucepan and stir into the dry ingredients. Pour into a well-greased and lined square tin, and bake in a moderate oven (325° F.) for about 1 hour.

## CAKE ICINGS

## Royal Icing

1 lb. icing sugar	A few drops acetic acid
About 2 egg-whites	

Sieve the icing sugar several times if at all lumpy. Make a well in the centre and stir in the lightly beaten whites of eggs. Add the small quantity of acetic acid and continue to beat vigorously until the icing is opaque and smooth.

## Glacé Icing

$\frac{1}{2}$ lb. sieved icing sugar	3 tablespoonfuls warm water
A few drops of flavouring essence	Colouring, if required

Put the sieved icing sugar and flavouring in an enamelled saucepan and add the water very gradually over a gentle heat. Stir till warm. Do not let the icing get too hot, or it will become crystallised. It should be thick enough to coat the back of a spoon. If too thin, more sugar should be added, or more water if too thick. Add colouring and use at once.

## Butter Icing

3 oz. butter or margarine	Vanilla essence
6 oz. sieved icing sugar	Colouring, if required

Cream the fat, add the sugar by degrees, beat until smooth and creamy, then add the flavouring and, if required, the colouring.

Coffee essence may be used in place of vanilla.

## Almond Icing

1 lb. ground almonds	1 teaspoonful vanilla essence
1 lb. icing sugar	
2 eggs	Juice of 1 lemon

Mix ground almonds and sugar together. Beat the eggs lightly and add them, with the flavouring essence and lemon juice, to the dry ingredients. Mix to a paste and knead well.

## PRESERVES

Jam must be made from fresh sound fruit, and when possible 1 lb. of sugar should be allowed to each pound of fruit. For fruit that is not rich in pectin it is necessary to add either a proportion of fruit rich in this essential or a little acid—usually citric or tartaric acid or lemon juice.

The fruit is first simmered to extract the pectin, and the sugar is then added. The jam is boiled and stirred until setting point is reached. The jam can be tested for setting by any of the following methods:

Pour a little jam on to a cold saucer. If a skin forms and wrinkles to the touch the jam is set.

When the jam falls in flakes and not drops from a wooden spoon it is set.

A thermometer can be used to find out the setting point, the average temperature being 220° F. Stir the jam evenly before the temperature is taken.

When the jam is ready to set pour it into clean, hot jars and cover at once with a waxed disc.

## Black-currant Jam

4 lb. black-currants	4 lb. sugar
2 pints water	

Remove the stalks, wash the fruit, and put it into a preserving-pan with the water. Simmer gently until it is tender and the contents of the pan are somewhat reduced. The skins of black-

currants are usually very tough, so it is important to cook the fruit thoroughly, until tender. Then add the sugar and stir until dissolved. Bring to the boil and boil briskly until the jam sets when tested on a cold plate. Pot and cover immediately.

## Strawberry Jam

(Using red-currant juice to increase bulk and aid setting)

1 $\frac{1}{2}$ lb. red-currants	2 lb. sugar
2 lb. strawberries	

Wash the currants, put them in a pan with a little water, simmer gently until tender, then pass them through a hair sieve to obtain the juice. Pick over the strawberries and put them in a pan with the currant juice and boil gently until tender. Add the sugar, stir until dissolved, and bring to the boil. Boil for about 10–15 minutes and test for jelling. Cool for 15 minutes before potting, to prevent the fruit from rising in the jars. Cover as usual.

## Apricot Jam

1 lb. dried apricots	The juice of 1 lemon
3 pints water	(or $\frac{1}{2}$ teaspoonful citric or tartaric acid)
2 $\frac{1}{2}$ –3 lb. sugar	

Wash the apricots thoroughly, put them into a basin with the water, cover, and leave to soak for at least 24 hours. Then put them into a preserving-pan with the water in which they were soaked and the lemon juice or acid. Bring to the boil, and boil gently for  $\frac{1}{2}$  hour, stirring occasionally. Add the sugar, stir until dissolved, and boil until the jam sets when tested on a cold plate: stir almost constantly after the sugar is added. Pot and cover immediately.

## Cherry Jam

(Using citric or tartaric acid)

4 lb. Mayduke	or $\frac{1}{2}$ oz. citric or tartaric acid
Morello cherries	
	3 lb. sugar

Stone at least two dozen cherries and remove the kernels. Put the kernels in a saucepan with the cherries and acid, and cook over a low heat to begin with; then bring to simmering point and simmer for  $\frac{1}{2}$  hour, or until the cherries are tender. Add the sugar, stirring while the contents of the pan come to the boil; boil fairly briskly for 10 minutes, then remove the stones. Test on a cold plate for jelling. As soon as it sets, pot in hot sterilised jars and cover immediately.

Note: As cherries are lacking in pectin the jam is only of light set.

## Gooseberry Jam

6 lb. slightly under-ripe gooseberries	2 pints water
	6 lb. sugar

Put the fruit and water into a pan. Heat slowly at first, and as the fruit gets soft break it with a spoon. Continue cooking until the contents of the pan have reduced by approximately one-third. Add the sugar, previously warmed in the oven, and stir until it dissolves, skimming if necessary. Boil gently for 15 minutes, then test on a cold plate for jelling. As soon as the jam sets pot and cover immediately.

## Plum Jam

3 lb. plums	3 lb. sugar
$\frac{1}{2}$ pint water	

Wash the fruit and cut in halves, removing the stones. Crack the latter to obtain the kernels. Put the water, kernels, and plums in a pan and bring very slowly to boiling point: simmer gently until the fruit is cooked. Add the sugar, stir until dissolved, and bring to the boil. Boil hard for about 10–15 minutes and test for jelling. Pot and cover as usual.

Note: If the plums are ripe, less water is required.

**Raspberry Jam**

3 lb. raspberries      3 lb. sugar

Place the fruit in a pan, heat gently at first (adding a very little water, if necessary), then simmer until the fruit is tender. Add the sugar, stir until dissolved, and bring to the boil. Continue to boil for about 15 minutes, or until the preserve jells on testing. Pot and cover as usual.

The principles of jam-making apply also to jelly-making, in particular, pectin, acid, and sugar must be present in the correct proportions. The fruit is boiled until it is soft and pulpy before being strained through a jelly bag, and allowed to drip overnight. The sugar is added to the juice, which is then boiled until a set is obtained.

**Apple Jelly**

4 lb. sharp apples      Water  
Juice of 1 lemon      Sugar

Windfalls can be used successfully, but sweet dessert apples do not contain sufficient pectin to produce a good set. Wash and remove any bruised or damaged portions, and cut into thick slices without peeling or coring. Put them in a pan with the lemon juice, and sufficient cold water to cover—2 quarts is approximately the amount required. Put over a low heat, bring to the boil, and simmer slowly until the apples are reduced to a pulp; then strain through a jelly cloth, leaving for several hours to drip. Measure the juice and put into a preserving-pan, with  $\frac{1}{2}$ -1 lb. of sugar to each pint. Bring to the boil, stirring meanwhile until the sugar has dissolved, and continue to boil briskly for 10 minutes. Test on a cold plate for jelling. Skim, pot, and cover immediately.

**Blackberry or Bramble Jelly**

4 lb. blackberries       $\frac{1}{2}$  pint water  
 $\frac{1}{2}$  oz. tartaric acid      Sugar

Wash the berries, which should not be over-ripe, and pick them over. Put them with the acid and water into a preserving-pan and bring to the boil. Cook slowly for 1 hour, or until the fruit is quite tender, mashing it occasionally. Strain through a jelly cloth. Measure the extract into a preserving-pan, add 1 lb. sugar to each 1 pint, stir until dissolved, and bring to the boil. Allow to boil briskly without stirring about 10 minutes, then test for jelling. Pot and cover at once.

**Quince Jelly**

3 lb. quinces       $\frac{1}{2}$  teaspoonful tartaric acid  
2 $\frac{1}{2}$  pints water      Sugar

Wash the fruit, remove and discard the core and pips, and cut into small pieces or mince. Put into a strong pan, with the water and tartaric acid, and stew slowly (this is most important) with the lid on the pan, mashing from time to time, until the fruit becomes tender. If necessary, more water must be added. When the pulp is tender and fairly thick, strain through a scalded jelly bag. Weigh the extract, put into a preserving-pan, and bring to the boil. Add an equal weight of sugar, and stir while it is coming to the boil again. Boil briskly for 10 minutes, then test on a cold plate for jelling. As soon as it sets remove from the heat, skim, pot, and cover immediately.

**Red-currant Jelly**

3 lb. red-currants      Sugar  
 $\frac{1}{2}$  pint water

Wash the fruit, but do not remove the stalks, and put into a preserving-pan with the water. Place over a very low heat and simmer gently until the fruit is thoroughly cooked and all the berries pulped. Strain through a jelly bag and allow to drip for several hours. Measure the extract, put it into a pan and bring to the boil. Add 1 lb. sugar to each pint of extract. Then cease stirring, allow it to boil briskly for about 7-10 minutes, and test for jelling. When the preserve jells pot and cover as usual.

Marmalades are made from citrus fruits, and as the skins are tough, prolonged boiling is required to soften the shredded skins, for this reason more water is added.

**Seville Orange Marmalade**

5 large or 6 small Seville oranges (about 2 lb.)      1 lemon or  $\frac{1}{2}$  teaspoonful citric or tartaric acid  
4 pints water      4 lb. sugar

Wash the fruit and cut it into shreds. Leave in a basin with the water overnight. Put the contents of the bowl into a deep saucepan or preserving-pan, bring slowly to boiling point, add the acid, if used, and simmer gently until the peel is soft and the contents of the pan reduced almost by half; this will take about 1 $\frac{1}{2}$  hours. Add the sugar, stir until dissolved, and then boil rapidly until a good set is obtained when a little marmalade is tested on a cold saucer. Allow to cool a little, and pour into hot, sterilised jars. Cover at once with waxed circles and then tie down.

**Sweet Orange Marmalade**

2 lb. sweet oranges      4 pints water  
 $\frac{1}{2}$  teaspoonful citric or tartaric acid      4 lb. sugar

Shred the oranges and put with the acid and water into a pan. Simmer gently until the rind is tender and the contents of the pan considerably reduced. Add the sugar, stirring until dissolved, and boil rapidly until a jelly is obtained when a little of the marmalade is tested on a cold plate. Pot and cover as usual.

**Grapefruit Marmalade (Thick)**

3 grapefruits (each weighing 10-12 oz.)       $\frac{1}{2}$  oz. tartaric acid  
4 medium-sized lemons      9 pints water  
5 lb. sugar

Wash the fruit thoroughly, cut it in half and squeeze out the juice. Shred the pith and rind thinly, but discard the cores and pips. Put the prepared rind and pith, the juice, tartaric acid, and water into a large pan or bowl. The next day boil in a preserving-pan slowly until the contents are reduced by half; this will take about 3 hours. Add the sugar and stir while bringing to the boil. Boil for 10 minutes, or until it jells when tested. Pot and cover as usual.

**PICKLES AND CHUTNEYS****Spiced Vinegar for Pickles**

To 1 quart of vinegar allow :

$\frac{1}{2}$  oz. blade of mace      6 peppercorns  
 $\frac{1}{2}$  oz. allspice       $\frac{1}{2}$  oz. root ginger (if a hot pickle is liked)  
 $\frac{1}{2}$  oz. cloves  
 $\frac{1}{2}$  oz. stick cinnamon

Tie the spices in muslin, place in a covered pan with the vinegar, and heat slowly to boiling point. Remove from the heat, leave to stand for 2 hours, and remove the spices before using.

**Pickled Cabbage**

Use red cabbage. Remove the outer leaves and shred finely. Place in a deep bowl, sprinkling the layers with dry salt, and leave for 24 hours. Drain, cover with cold spiced vinegar, and leave for a further 24 hours, mixing occasionally. Pack and cover as usual.

**Pickled Onions**

Use small pickling onions. Remove the skins carefully, without cutting the onions, wash, cover with brine, and leave for 24 hours. Drain, wash and dry, put into jars, and cover with cold spiced vinegar. Seal as usual.

**Piccaililli**

3 lb. green tomatoes      1 oz. mustard  
1 cauliflower      1 teaspoonful mustard seed  
2 cucumbers      1 quart vinegar  
1 lb. onions      1 teaspoonful pepper-corns  
Salt  
8 oz. sugar  
 $\frac{1}{2}$  oz. turmeric

Cut up the vegetables into small pieces and place in layers in a basin alternately with layers of salt. Let stand overnight and then drain. Boil together the vinegar, sugar, turmeric, and mustard, together with the mustard seed and peppercorns

tled in a muslin bag. Add the vegetables and heat through without boiling. Remove the muslin bag, pack the pickle into sterilised jars, and seal. Store for about a month before using.

#### Green Tomato Chutney

3 lb. green tomatoes      ½ oz. mustard seed  
 ½ oz. salt                    ½ teaspoonful pepper  
 4 oz. prunes or sultanas   ½ teaspoonful mixed  
 6 oz. chopped onion       pickling spice  
 6 oz. chopped apple       4 pints vinegar  
 6 oz. sugar

Wipe or wash the tomatoes and remove the stalks and stalk ends. Chop them small or pass them through a mincing-machine, then put them into a basin in layers with the salt, cover, and leave to stand overnight. Soak the prunes also, if used. The next day drain off the liquid and turn the tomatoes into a preserving-pan. Stone and chop the prunes and add to the tomatoes, with all the other ingredients. Cook slowly, stirring occasionally, until reduced to a soft pulp; the time required will be about 2 hours. Then pot and cover.

#### Marrow Chutney

3 lb. marrow                2 tablespoonfuls salt  
 ½ lb. shallots               12 peppercorns  
 ½ lb. green apples         ½ oz. bruised root ginger  
 ½ lb. sultanas, if avail-   4 oz. sugar  
   able                        1½ pints vinegar

Cut up the marrow, place in a basin, sprinkle with the salt, and leave for 12 hours; drain and rinse thoroughly. Peel and chop the shallots and apples finely and add the sultanas. Tie the spices in muslin. Put all the ingredients in a saucepan, bring slowly to the boil, and simmer gently until the chutney is cooked and of the correct consistency. Pot and cover.

Note: Cinnamon and allspice may be added to this chutney, if liked.

#### FRUIT BOTTLING

Fruit for bottling must be in perfect condition. It should be washed and packed tightly into clean preserving-jars. The patent lids and rubber rings must be examined carefully before sterilising takes place. Water or syrup made from water and sugar is used for bottling. The average proportion for syrup is 6-8 oz. sugar to 1 pint of water. To prepare this, boil the sugar and water in a covered pan for 1 or 2 minutes and then strain through muslin.

Sterilisation by one of the following methods is carried out to destroy any moulds or bacteria.

#### Sterilising under Water

After the fruit has been packed in the bottling-jar, cover it with cold water or syrup. Put the tops and rubber bands in position and adjust metal clips or screw bands. Screw bands should be given one half-turn back after they have been screwed on to allow for expansion of glass during the sterilisation. Place the bottles in a deep vessel, standing them on wooden slats or a similar "false bottom," taking care that they do not touch each other. Fill the pan with cold water to come at least to the neck of the bottles. Heat

gently to required temperature, taking approximately 1½ hours to reach this point. Maintain temperature as shown in the following table. Remove the bottles from the water and tighten the screw bands. The next day remove bands or clips and test for a seal.

#### TIME AND TEMPERATURE CHART FOR STERILISING FRUIT

(For use when bottling fruit by sterilising under water.)

Fruit.	Temperature to which water should be raised in 1½ hours (in degrees Fahrenheit).	No. of minutes this temperature should be maintained.
Apples . . . . .	165°	10
Apricots . . . . .	165°	10
Blackberries . . . . .	165°	10
Cherries . . . . .	190°	10
Currants (black, red or white) . . . . .	180°	15
Damsons . . . . .	165°	10
Gooseberries . . . . .	165°	10
Greengages . . . . .	165°	10
Loganberries . . . . .	165°	10
Mulberries . . . . .	165°	10
Peaches . . . . .	165°	10
Pears . . . . .	190°	20
Plums (ripe, whole) . . . . .	165°	10
Plums (under-ripe or halved) . . . . .	165°	20
Quinces . . . . .	190°	20
Raspberries . . . . .	165°	10
Rhubarb . . . . .	165°	10
Strawberries . . . . .	165°	10
Tomatoes . . . . .	190°	30

#### Sterilising by the Oven Method

Pack the fruit in the jars, cover each with patty tin, and stand on a baking-tin in a cool oven (240° F.). Leave for about ½ hour, or until the fruit has shrunk, changed colour, and appears cooked. If the shrinkage is considerable fill one jar up from another and replace in the oven for 5-10 minutes. Remove the jars one by one from the oven and fill to the brim with boiling syrup or water. Put on rubber bands, tops, and clips or screw bands. Leave before testing as before.

#### Vegetable Bottling

Vegetables may be preserved by bottling, provided a pressure cooker is used to sterilise them. They should be prepared according to type, and blanched before being packed into jars. Blanching is done by tying the vegetables in muslin and plunging them into boiling water for a few minutes, and then plunging into cold water. For sterilising follow the directions given in a reliable pressure-cooker instruction book. The following table shows the times required for blanching and sterilisation:

TABLE FOR BLANCHING AND STERILISING VEGETABLES

Vegetable.	Blanching time.	Sterilising time (1 pt. bottles, 10 lb. pressure).
Asparagus . . . . .	2-3 minutes in boiling water	30 minutes at 240° F.
Broad beans . . . . .	2-3 minutes in boiling water	35 minutes at 240° F.
Beetroot . . . . .	10-30 minutes in boiling water	35 minutes at 240° F.
Carrots . . . . .	10-15 minutes in boiling water	35 minutes at 240° F.
Celery . . . . .	5 minutes in boiling water containing ¼ level teaspoonful citric acid per quart	30 minutes at 240° F.
French beans or runner beans	3 minutes in water at 180° F.	35 minutes at 240° F.
Mushrooms . . . . .	Stew in a casserole	30 minutes at 240° F.
New potatoes . . . . .	5 minutes in boiling water (remove skin first)	40 minutes at 240° F.
Peas (fresh) . . . . .	1-2 minutes in boiling water	40 minutes at 240° F.
Vegetable macedoine . . . . .	According to the individual types	40 minutes at 240° F.

## V. REFERENCE TABLES

## Basic Proportions

**Pastry**  
*Suet Crust.* 1 lb. flour, 2 teaspoonfuls baking-powder, 6-8 oz. suet, cold water to mix.  
*Short Crust.* 1 lb. flour, 8 oz. fat, cold water to mix, pinch of salt.  
*Flan.* 1 lb. flour, 10 oz. fat, 1 teaspoonful sugar, 1 yolk of egg, cold water to mix.  
*Flaky.* 1 lb. flour, 10-12 oz. fat, pinch salt, lemon juice, approx.  $\frac{1}{2}$  pint cold water.  
*Rough Puff.* 1 lb. flour, 8-12 oz. fat, pinch salt, lemon juice, approx.  $\frac{1}{2}$  pint cold water.  
*Puff.* 1 lb. flour, 1 lb. butter, lemon juice, salt, cold water to mix.  
*Hot-water Crust.* 1 lb. flour,  $\frac{1}{2}$  lb. fat, salt,  $\frac{1}{2}$  pint milk or milk and water.

## Steamed Puddings

*Suet.* 4 oz. flour, 4 oz. fresh breadcrumbs, 1 teaspoonful salt, 4 oz. suet, 2 oz. sugar, approx.  $\frac{1}{2}$  pint milk to mix.  
*Plain Sponge.* 8 oz. flour, 2 teaspoonfuls baking-powder, 2-3 oz. fat, 1 oz. sugar, milk or milk and water to mix.  
*Sponge.* 3 oz. fat, 3 oz. sugar, 1 egg, 5 oz. flour, 1 teaspoonful baking-powder.

## Batter Puddings

*Yorkshire Pudding and Pancakes.* 4 oz. flour, 1 egg, salt,  $\frac{1}{2}$  pint milk.  
*Coating Batter.* 4 oz. flour, 1 egg, salt,  $\frac{1}{2}$  pint milk.

## Milk Puddings

*Powdered Grain.* 1 pint milk,  $1\frac{1}{2}$  oz. grain.  
*Ground Grain.* 1 pint milk,  $1\frac{1}{2}$  oz. grain.  
*Whole Grain.* 1 pint milk,  $1\frac{1}{2}$  oz. grain.

## Custard

*Baked.* 1 egg,  $\frac{1}{2}$  pint milk.  
*Steamed.* 1 egg,  $\frac{1}{2}$  pint milk.  
*Cup.* 1 egg,  $\frac{1}{2}$  pint milk.

## Cakes

*Plain.* 1 lb. flour, 4-8 oz. fat, 4-8 oz. sugar, 4-8 oz. fruit, 2-4 eggs, 2-3 teaspoonfuls baking-powder,  $\frac{1}{2}$  teaspoonful salt, milk to mix.  
*Rich.* 1 lb. flour,  $\frac{1}{2}$ -1 lb. fat,  $\frac{1}{2}$ -1 lb. sugar, 4-8 eggs, 1 teaspoonful baking-powder,  $\frac{1}{2}$ -3 lb. fruit, milk to mix.  
*Sponge.* 1 egg, 1- $1\frac{1}{2}$  oz. sugar, 1 oz. flour.  
*Gingerbreads.* 1 lb. flour,  $\frac{1}{2}$  teaspoonful salt,  $1\frac{1}{2}$  teaspoonfuls ground ginger, 2 teaspoonfuls baking-powder,  $\frac{1}{2}$  teaspoonful bicarbonate of soda, 8 oz. brown sugar, 6 oz. margarine,  $\frac{1}{2}$  lb. treacle,  $\frac{1}{2}$  pint milk, 1 egg.

## Sauces

*Pouring.*  $\frac{1}{2}$  oz. fat,  $\frac{1}{2}$  oz. flour,  $\frac{1}{2}$  pint liquid.  
*Coating.* 1 oz. fat, 1 oz. flour,  $\frac{1}{2}$  pint liquid.  
*Panada.* 2 oz. fat, 2 oz. flour,  $\frac{1}{2}$  pint liquid.

## Homely Measures

Flour, Cornflour. 2 level teaspoonfuls.  $\frac{1}{2}$  oz.  
 Cocoa, Custard 1 level tablespoonful  $\frac{1}{2}$  oz.  
 Powder 2 level tablespoonfuls 1 oz.  
 1 teacupful 3  $\frac{1}{2}$  oz.  
 1 breakfast cupful 5 oz.

Sugar, Rice, 1 tablespoonful 1 oz.  
 Lentils, etc. 1 teacupful 8 oz.  
 1 breakfast cupful 8 oz.  
 Breadcrumbs, etc. 2 level tablespoonfuls  $\frac{1}{2}$  oz.  
 Liquids 1 teacupful  $\frac{1}{2}$  pint  
 1 tumblerful or breakfast cupful  $\frac{1}{2}$  pint

## British Standard Measures

## Cup Measures

A British Standard Cup contains 10 fluid ounces, i.e., one half-pint, a Standard Tablespoon  $\frac{1}{4}$  of a fluid ounce. Standard Measures should be filled level.

Flour 1 cup 5 oz.  
 Semolina 1 cup 6  $\frac{1}{2}$  oz.  
 Sugar (granulated) 1 cup 8 oz.  
 Fat 1 cup 8 oz.  
 Breadcrumbs (fresh) 1 cup 2  $\frac{1}{2}$  oz.  
 Liquid 1 cup  $\frac{1}{2}$  pint  
 Golden Syrup 1 cup 1 lb.  
 Sultanas 1 cup 6 oz.

## American Standard Measures

These are based on the American pint of 16 fluid ounces. For a recipe given entirely in cup measurements use either British or American Standard Cups, provided the same measuring system is used throughout.

## Avoirdupois and Liquid Measures

## Avoirdupois

16 drs. 1 oz.  
 16 oz. 1 lb.  
 28 lb. 1 qr.  
 4 qrs. 1 cwt.  
 20 cwt. 1 ton  
 14 lb. 1 stone  
 8 stone 1 cwt.  
 112 lb. 1 cwt.

## Liquid Measures

4 gills 1 pint  
 2 pints 1 quart  
 4 quarts 1 gallon

Note: 1 pint of water weighs  $1\frac{1}{2}$  lb.

## Liquids

Boiling 212° F.  
 Simmering 200-210 F.  
 Slow simmering 180-190° F.  
 Blood Temp. (also called tepid and lukewarm) 98.4° F.

## Cooking Temperatures

## Ovens

Slow oven 275-325° F.  
 Moderate oven 325-375° F.  
 Moderately hot oven 375-425° F.  
 Hot oven 425-475° F.  
 Very hot oven 475-500° F.

## Electric Cookers

With thermostatically controlled electric ovens it is usually found that the thermostat scale is marked either in degrees Fahrenheit or in Numbers 1, 2, 3, etc., corresponding with 100° F., 200° F., 300° F., etc.

## Gas Ovens

## THERMOSTATIC SETTINGS FOR WELL-KNOWN MAKES OF GAS COOKERS

Name of stove.	250° F.	300° F.	350° F.	400° F.	450° F.	500° F.
Radiation New World "Regulo"	$\frac{1}{2}$ -1	1-2	3-4	5-6	7-8	9-10
Main Cooker "Mainstat"	$\frac{1}{2}$ -1 or AB	1-2 or C	4 or D	6 or F	8 or G	10-11 or J
Parkinson Stove "Ajusto"	1	3	4-5	6	7-8	8-9
Flavel Kabinat "Thermo tat"	B	C-D	E-F	G	H-I	J
New Herald "Thermostat"	$\frac{1}{2}$	1-2	4	6	8	10-11
Newhome "Autokook"	$\frac{1}{2}$ -1	1-2	4	6	8-9	10
Cannon Champion "Autimo"	$\frac{1}{2}$ -1	1-2	3-4	6	8-9	11

Note: Most new gas cookers will have thermostats showing standard markings as follows:

Setting	$\frac{1}{2}$	$\frac{1}{2}$ -1	1	2	3	4	5
° F.	241	266	291	313	336	358	379
Setting	6	7	8	9	10	11	12
° F.	403	424	446	469	491	513	536

## VI. HOUSEHOLD HINTS

### Cleaning—Choice of Equipment

Reliable and well-designed cleaning equipment is of prime importance to the housewife. When buying take time going over each point carefully and handle the appliance when possible. It should be of sound construction, simple to operate, and easy to clean. The following points should help towards a wise choice:

**Vacuum Cleaners.**—There are two main types of vacuum cleaner, the one with a long handle which is pushed over the floor like a broom, and the other generally a cylinder-shaped machine with an enclosed dust-bag. For houses with large carpeted areas the long-handled type is usually most satisfactory, and in smaller houses where there is a good deal of furniture and rugs the cylindrical type is a good choice. General points to watch for are a simple design with no dust-traps, a comfortable handle, a machine that is not too heavy or noisy, attachments that are easy to assemble, and a dust-bag that can be easily removed.

In all cases, vacuum cleaners should be used according to the manufacturers' instructions to obtain the maximum efficiency. Unless the cleaner is of the self-adjusting type, nozzles of long-handled cleaners must be adjusted to suit the kind of carpet being cleaned. Dust-bags must be emptied regularly and brushes kept clean and free from hair. Check up on the cord and connection regularly.

**Carpet Sweepers.**—These are valuable for everyday cleaning. They should be soundly constructed and streamlined for easy cleaning. The sweeper should be simple to empty, and should not have too shallow a dust-collecting pan. The brush should be adjustable so that as it becomes slightly worn it still maintains good contact with the carpet.

**Dusting-mop.**—This should have a detachable head made of lightly twisted yarn which will not shed fluff. Mops with a flexible handle save a good deal of stooping. Mops should be washed regularly in hot, soapy water.

**Wet Mop.**—Self-wringing mops are available, and these are a great convenience. Alternatively, if choosing a mop and bucket make sure that the special wringing plate is so placed that the bucket is well balanced.

**Brooms and Brushes.**—It is well worth buying good brushes with a full head of hair or fibre. Handles should be placed at a convenient angle and be long enough for easy use. Brooms and brushes should be stored in such a way as to avoid the weight resting on the head.

**Scrubbing-brushes.**—Choose those with a good grip and sufficient clearance for the knuckles.

**Floor Polishers.**—Electric floor polishers are extremely useful if fairly large areas of polished floors are involved. The three-brush type is a good choice for big floors, whereas the two-brush or cylinder-brush type is usually lighter and easier to handle when polishing surrounds. Hand-operated polishers are also available with a special device for spreading the wax.

### PLANNING HOUSEWORK

A planned routine is the basis of all good housework, and much labour can be saved if the daily and weekly jobs are carried out systematically. Simple alterations or re-arrangements can save both time and work, particularly in the kitchen.

The general order of daily work is much the same in all rooms.

1. Collect tools and a tray or basket for waste paper, cigarette ends, etc.
2. Open windows to air room; tidy up.
3. Run carpet sweeper over rugs and carpet.
4. Dust and mop surrounds, ledges, and furniture.
5. Replace everything.

**Bathroom.**—Wipe out bath and basin with a non-scratchy cleanser. Give lavatory a good brush and flush.

**Bedroom.**—Air beds before making.

**Living-room.**—Attend to grate and re-lay fire. Polish heavily used furniture.

**Stairs and Landing.**—Close all doors, start upstairs and work downwards.

Each room should be thoroughly "turned out" once a fortnight, and the following routine can be adapted for most rooms, with reference to the special cleaning needs below:

1. Open windows.
2. Remove flowers, empty ashtrays, waste-paper basket, etc.
3. Attend to the fireplace.
4. Vacuum-clean curtains, upholstery, and carpets.

If a vacuum cleaner is not available:

- (i) cover upholstered or covered furniture;
  - (ii) shake curtains gently;
  - (iii) clean the carpet with a carpet brush.
5. Mop and polish surrounds if any.
  6. Clean the windows. Wash finger-marks, etc., from paintwork where necessary.
  7. Dust window-ledges, wainscoting, etc.
  8. Dust all polished furniture (polish when necessary).
  9. Shake rugs, etc., in open air, and replace everything.

**Bedroom.**—Strip and air bed. Dust, brush, or vacuum the bedstead and mattress. Remake bed.

**Bathroom.**—Clean the bath and hand-basin by running a little hot water into the bath, and then with a cloth and paste cleanser rub off the dirty marks; rinse well, and dry with a basin cloth. Rub over the taps with a damp cloth and dry with a duster.

**Lavatory.**—Once a week pour hot strong soda water (1 tablespoonful soda to 1 quart boiling water) down the lavatory pan, brush vigorously. Flush.

**Kitchen.**—Keep the sink cleaned regularly with hot soapy water and a stiff brush. Once a week clean thoroughly with very hot strong soda water. If the sink becomes badly discoloured use a proprietary chlorine bleach according to manufacturers' directions, rinsing carefully afterwards.

Gas and electric cookers should be washed each week with a soapless detergent. Steel wool can be used to remove obstinate marks. Badly neglected cookers may require treatment with a caustic-soda preparation, in which case manufacturers' directions must be followed.

Clean the flues of solid-fuel cookers regularly.

The larder should have easily cleaned surfaces; wooden shelves can be lined with linoleum, oil-cloth, or laminated plastic. The window should be adequately screened with perforated zinc or muslin to exclude flies. Special cleaning is necessary once a week. Remove all food and wash the shelves and floor; clean window, containers, and woodwork. Replace the food when the larder is dry. Perishable food stored in the larder should be examined every day.

Refrigerator must be de-frosted once a week, according to manufacturers' instruction. Remove all food, and wash the interior out with luke-warm water to which a little bicarbonate of soda has been added. It is important to place food correctly in a cabinet, the strong-smelling foods should normally be on the higher shelves, and moist foods should be covered to prevent drying.

### SPECIAL CLEANING HINTS

**Stains on Bath.**—Blue marks from a geyser can be removed by rubbing with a cloth dipped in vinegar, followed by rinsing. To remove rust marks treat with oxalic acid (1 teaspoonful to 1

pint hot water). Apply directly over the mark with an old mop or brush, and rinse quickly and thoroughly. Oxalic acid is very poisonous, and must be used with great care.

**Paintwork.**—Wash with warm water and soapless detergent. Work from the highest point downwards. Remove stains with a paste cleanser, rinse, dry, and apply furniture cream sparingly.

**Windows.**—Wash with a leather wrung out of luke-warm water and polish with a fluff-free cloth. Alternatively, use a proprietary window-cleaning preparation.

**Linoleum.**—Avoid scrubbing, which will tend to make the linoleum brittle. Treat with wax polish or a water-wax emulsion. Obstinate marks can be removed by rubbing with medium-grade steel wool dipped in turpentine.

**Rubber Floors.**—Use a special rubber-floor polish or water-wax emulsion. Clean with a paste cleanser, and avoid wax polishes, as they contain rubber solvents.

**Composition Floors.**—Treat with water-wax emulsion or special polish supplied or recommended by manufacturers. Avoid washing and scrubbing.

**Upholstered Furniture.**—Brush or clean with vacuum cleaner and if generally soiled shampoo the furniture. Whisk up a good lather using soap or a soapless cleanser; work on a small area, apply the lather with a brush, working well in. Scrape off any excess lather with the back of a knife and rinse with a cloth wrung out of clear water. Avoid saturating the material, and leave the windows open to ensure quick drying.

**Hide Suites.**—Polish with furniture or shoe cream, rubbing up well. Occasionally sponge with a mixture of 1 teaspoonful strong ammonia and 4 teaspoonfuls vinegar, added to 1 quart of water. Afterwards apply a little castor oil, rubbing well in, when dry polish as before.

**Leathercloth or Rexine.**—Sponge over with a damp cloth when soiled, and rub up with a clean duster. Avoid using polish.

**Brass and Copper.**—Clean regularly with a reliable metal polish. Slightly neglected metal should be washed in hot, soapy water, before polishing. Use a brush to clean the crevices. Badly neglected brass or copper articles can be treated with a solution of spirits of salts diluted five to six times with water. Apply with an old brush, and do not allow the solution to come in contact with anything but the metal. Rinse very thoroughly and polish when dry. Use and store spirits of salts with great care, as the solution is very poisonous.

**Bronze.**—Dust well, and if necessary apply a little oil, rubbing it in well. Polish up with a soft duster, taking care to remove all traces of oil.

**Gilt.**—Clean with a cloth dipped in a little turpentine.

**Lacquered Articles.**—Rub occasionally with a little furniture cream. Never use metal polish, which will remove the lacquered finish.

**Silver and Silver Plate.**—Polish regularly with prepared non-scratchy polish or impregnated cloth. Wash table silver in warm, soapy water after cleaning. Badly neglected articles which will not be harmed by immersion in boiling water can be cleaned in the following way. Half-fill an old aluminium saucepan with water and bring to the boil, then add 2 oz. soda to each gallon of water. Immerse articles in the boiling water. Remove after a few minutes, wash in warm, soapy water, rinse, and dry.

**Stainless Steel.**—Rub up with a soft, dry duster, and wash if necessary with warm, soapy water.

Stainless-steel sinks can be polished with a paste cleanser or finely powdered whitening.

## HOME LAUNDRYWORK

**Choice of Equipment.**—The labour of washing at home is greatly reduced by the choice of good equipment. The first essentials are a good deep sink, a strong wringer, a reliable iron, and steady ironing-board. A plentiful supply of hot water should be available, and some provision made for boiling white cotton and linen goods. Drying out of doors is ideal, and a good strong clothes line is required for this. Where out-door drying is not possible, choose a ceiling or wall alriner which will not be in the way indoors.

Washing-machines are becoming increasingly popular, and the choice is now wide. A good machine saves a tremendous amount of back-breaking work, and the type and size should be chosen to suit individual needs. Generally speaking, machines can be classed in the following categories:

(a) *Automatic and Semi-automatic.*—These machines have a spin-dryer incorporated, which extracts the moisture from the clothes, leaving them ready to hang out. Washing, rinsing, and spin-drying are carried out in the machine, obviating handling of wet clothes between the processes. Fully automatic machines must be bolted to the floor and fixed with special taps. They will take a load of 8-10 lb. dry washing.

(b) *Electrically Operated Machines with Electric Wringer.*—These machines are mobile, and are filled by hand or by means of a hose. Some are fitted with an emptying pump. The electric wringer is reversible and placed on a swivel so it can be swung over the sink. Two or more loads of 7-10 lb. dry washing can be done in the same lot of suds.

(c) *Electrically Operated Machines with Hand Wringers.*—These are similar to the above type without a power wringer. They are fitted with a well-sprung hand-wringer, making them less expensive to buy. In this category are small machines designed to fit under a draining-board. The load of dry washing varies from 3 to 10 lb., according to the size of the machine.

(d) *Gas or Electrically Heated Machines with a Hand-operated Wringer and Agitator.*—These, though less labour saving than the above types, are useful where the hot-water supply is limited. The water is heated in the machine, and the agitator is worked by hand. A hand-wringer can be fitted on these machines. Load about 6 lb. dry washing.

(e) *Hand-operated Machines.*—These are the simplest form of washing-machine, being hand-filled and fitted with hand-operated agitator. No water-heating device is incorporated.

Ironing equipment requires careful selection, and individual preference for the size and shape of an iron is important. An electric iron should be well balanced and comfortable to hold. It should be sufficiently pointed to iron gathers, etc., easily, and the heat-control dial must be clearly marked.

The normal weight for an iron is 4½-5 lb., though for ironing table linen some people prefer a heavier iron, of say, 6 lb. Gas, petrol, and flat irons serve as an alternative where electricity is not available. Modern gas irons are adapted for a certain amount of heat control. The average height of an ironing-board is 32 in., and this is comfortable for most people. It should be simple to fold away, and really firm when standing.

The choice of soap is important for laundry-work. For the general family wash pure laundry soap is a good choice. It should be shredded with a grater and dissolved in hot water beforehand to make a soap jelly. Soap powders are particularly useful for washing white articles that are slightly discoloured. Soap flakes have the advantage of being readily dissolved in warm water, and are free from excess alkali, so that they can be safely used for delicate fabrics. Soapless detergents available in liquid or powder form are now widely used. Not all varieties are suitable for the white wash, and this fact is usually clearly stated by the manufacturers. These detergents are especially useful in hard-water districts, as they do not react

with the hard water in the way soap does, and no scum is formed. It is not, therefore, necessary to soften the water, and rinsing is easier.

In hard-water districts water should be softened for laundrywork when soap is used. Soda is a suitable and cheap water softener, provided it is used in the correct proportions. The solution must allow for no free soda, and must be added to hot water five minutes before the addition of soap. The following proportions are correct for a stock solution.

Heat 1 quart of water and dissolve in it 2 oz. of washing soda. Leave to cool before bottling. One tablespoonful of this solution will be required for each gallon of water of 10 degrees hardness.

**The Family Wash.**—Collect up all the articles. Empty all pockets and attend to stains, major tears, etc. Then sort articles into groups, according to the nature of the fabric or degree of soiling. The order of washing should be as follows:

Table linen and other lightly soiled articles.

Fine articles of personal wear.

More heavily soiled items, such as shirts, bath towels, etc.

Overalls, oven cloths, dusters, etc.

Woollens should be done separately.

Heavily soiled articles can be soaked overnight in order to loosen the dirt.

Sufficient soap should be added to the water to give a good lather. The lather should remain during the whole washing process if results are to be satisfactory. If necessary, prepare fresh water during the wash. For best results linens and cottons require washing in water approximately 105–110° F. Lower temperatures are preferable for coloured articles, silks, and woollens.

Each garment should be opened out before dropping it into the washing water, and the sink should not be overfilled with clothes. When using a washing-machine, manufacturers' instructions must be carefully followed. Do not overload a washing-machine. The washing time varies according to the fabric and degree of soiling, but cleansing is as a rule complete after 5–7 minutes. Woollies and silks require less time, and must on no account be left too long in a machine. Collars, cuffs, and soiled areas should be moistened and rubbed with soap before placing the garment in the machine.

When washing by hand, linens and cottons can be rubbed, kneaded, and squeezed. A soft nail brush is a help towards removing any specially dirty mark. For silks and woollens see later instructions.

If possible wring the articles before rinsing, and then again between each rinse. For satisfactory results continue rinsing until the last water is clear and free from all traces of soap.

In order to keep white cotton and linen articles a good colour they should be boiled at least every third wash. The washed articles are put into the boiler with warm, softened, soapy water, and brought to the boil, and boiled for 15–20 minutes. For badly discoloured articles add borax (1 ounce to 1 gallon) to the water and stew the articles for as much as an hour. Rinse as above and line white articles.

Some soap powders contain new opalescent ingredients, and when these are used bluing is unnecessary.

Ultramarine blues are on the whole most convenient for laundrywork. Add the blue to the water, stir well, and test by immersing a piece of white rag and squeezing it out. Alternatively, scoop some of the blue water out by hand and judge the strength by the colour, which should be a deep but not dark blue. Over-bluing with ultramarine blues can be rectified by soaking the article in vinegar and water. Soluble blues are as a rule coal-tar dyes, and although they give even results, excess blue can be removed only by bleaching.

Dip the articles once or twice into the blue bath, but do not allow them to remain lying in it. Stir the water occasionally to prevent particles settling on the base of the bath.

Starching is required to re-stiffen cotton and linen articles. Starched articles will also resist dirt and keep clean longer. The thickness of starch required depends largely on the quality and age of the material. For ordinary purposes a cooked or boiling-water starch is used in the following way:

Mix 1 tablespoonful of starch into a smooth paste with 3 tablespoonfuls of cold water. Pour on boiling water until the starch clears, stirring all the time. This full-strength starch is diluted, according to the degree of stiffness required, as follows—

1 part full-strength starch to 4 or 5 of water for table linen, soft collars, thin or medium-weight linen or cotton curtains.

1 part full-strength starch to 8 of water for bed-linen, shirts, or frocks.

Immerse the rinsed and wrung article in the starch solution, allowing it to become thoroughly saturated. For extra stiffness dry the article before starching.

For stiff glazed collars, cuffs, and shirt fronts use unboiled or cold-water starch in the following way:

Mix 2 tablespoonfuls of powdered starch with 3–4 tablespoonfuls of water taken from a measured pint. Add the remaining water and strain through muslin. Allow the starch to stand to soften the starch grains. Immerse the article in the solution and rub the starch well into the material. Iron when still very damp on a board with no blanket. A hot iron is required to burst the starch grains. To get a good finish, a glossing iron with curved heel and toe is necessary.

Plastic starches give a stiffness which lasts through several washes. They give a matt finish, and are not suitable for articles requiring gloss. Follow manufacturers' instructions.

Dry clothes in the open air whenever possible. It is important to avoid direct sunlight, for coloured articles, and white silks and woollens. Hang to avoid unnecessary strain on the fabric; generally speaking, garments should be hung from the shoulders.

**Ironing.**—The chart below shows the degree of dampness and temperature of iron required for different fabrics.

IRONING CHART

Fabric.	Degree of dampness.	Side on which to iron and temperature of iron.
Cotton	Slightly damp	Right side (unless dark-coloured) with hot iron
Voile	Damp	Wrong side with fairly hot iron
Organdie	Damp	Right side with hot iron
Linen	Damp	Right side with hot iron
Crease-resisting linen	Slightly damp	Right side with coolish iron
Silk	Slightly damp	Wrong side with warm iron
Tussore silk, shantung	Dry	Wrong side with fairly hot iron
Rayon (duff and suede finish)	Dry	Wrong side with coolish iron, if necessary over a slightly damp cloth
Satin rayon	Damp	Wrong side with coolish iron
Linen-type rayon	Damp	Wrong side with coolish iron
Rayon marocains and georgettes	Damp	Wrong side with coolish iron, stretching fabrics gently
Knitted rayon	Slightly damp	Either side with cool iron, across fabric to prevent dropping
Nylon	Nearly dry	Either side with cool iron

The following fundamental points should be watched :

1. The articles must be at the right degree of dampness. Ideally they should be taken off the line and rolled up before they are too dry. If damping down is necessary, roll the articles up again and leave for about an hour. Rayons should never be damped down, it is better to re-immense the garment.

2. Iron the articles until quite dry.

3. Place the article on the ironing-board to avoid as much turning as possible.

4. Iron all double parts first, and then small parts such as belts, collars, etc.

5. Iron the article lengthways along the selvage. The exceptions to this rule are net curtains and some rayons, which should be ironed diagonally.

6. Look over the article when finished and touch up creased parts.

7. Fold carefully and air before putting away.

### Treatment of Special Items

**Woolens.**—Tack round hand-knitted garments before washing. Use warm water, keeping the same temperature for rinsing and washing. Do not rub, and rinse in several changes of water. Fold in a towel before passing through the wringer. Dry flat away from direct heat.

**Blankets.**—Choose a fine breezy day to ensure quick drying. Use a large sink or bath so that the blanket can move freely in the washing water. Maintain a live lather throughout washing; it may be necessary to use two washing waters. Wring before rinsing in at least two clear waters. Shake well and hang out to dry. Striped blankets must be hung so that the stripes run up and down. Shake during the drying to bring up the nap.

**Stiffening Silks.**—Use a solution of gum arabic made in the following way. Dissolve 4 oz. gum arabic in 1 pint water. Strain and use 1-4 teaspoonfuls of the solution to each  $\frac{1}{2}$  pint of rinsing water. Iron while the material is still very damp.

**Handkerchiefs.**—Soak in cold salt water for  $\frac{1}{2}$  hour. Rinse before washing. To improve the colour, stew in soapy water and borax (1 table-spoonful to  $\frac{1}{2}$  gallon) for  $\frac{1}{2}$  hour. Rinse well and starch lightly.

**Socks.**—Soak for 15 minutes in warm water and borax. Wash in soapy water, rinse well and pull into shape.

### Removing Stains

The following general rules and the ready reference chart below may help to solve this difficult problem :

1. Stains should be tackled soon after they occur, for if left they are apt to set and become more difficult.

2. Check up on the nature of the staining matter and the type and colour of the material. It is wisest to try the simplest method of removal first.

3. When dealing with delicate or coloured material, first try out the treatment on a hidden corner.

4. Short, repeated treatments are less likely to cause damage to the fabric, so be patient and very persistent.

5. Be sure to remove thoroughly the chemical used for treating the stain, or the fabric may be damaged. (Grease solvents, of course, evaporate without further treatment.)

6. Handle the chemicals carefully, especially those such as oxalic acid and salts of lemon, which are poisonous.

### COMMON STAINS AND THEIR TREATMENT

Stain.	Treatment.
Acid . . . . .	Sponge with warm water to which a little ammonia has been added.
Blacklead . . . . .	Sponge with turpentine, then wash in the usual way.
Blood . . . . .	Soak in cold salt water (1 tea-spoonful to 1 pint) for about an hour. Wash in cool soapy water. Any resistant or old stains will require to be treated with oxalic acid or salts of lemon solution (see "Iron Mould").
Candle grease . . . . .	Scrape off "crust" and then sponge with cleaning benzine.
Cocoa . . . . .	Treat as for tea stain.
Cod liver oil . . . . .	Treat as for grease marks, and wash if possible. Any remaining stain will need to be bleached with hydrogen peroxide (20 vol. diluted 1 part in 5 of water). Soak 10-15 minutes and wash in the usual way.
Coffee . . . . .	Treat as for tea stain. If non-washing material rub in a little glycerine, removing any excess with methylated spirits. (Test rayons before treating.)
Creosote . . . . .	Sponge with benzol or eucalyptus oil.
Fruit . . . . .	Treat as for tea stain.
Grass . . . . .	Sponge with methylated spirits.
Gravy . . . . .	Sponge with a grease solvent and wash in warm, soapy water. Rinse well.
Grease . . . . .	Lay the stained area over a pad of absorbent material and dab sparingly with grease solvent such as carbon tetrachloride. Start well outside the mark and work towards the centre, in order to prevent "ringing." Shake to hasten evaporation. Avoid inhaling the fumes of carbon tetrachloride, and keep the bottle tightly corked.
Ink :	
Writing ink	Washable Fabrics should be rinsed immediately in cold water. Any remaining traces of stain will require a bleach as follows :
	White Linens and Cottons : Apply a solution of chlorine bleach immediately over the mark. After a few minutes rinse thoroughly and boil.

Stain.	Treatment.	Stain.	Treatment.
Ink (contd.):		Nail Polish	Sponge with acetone. (Test rayons before applying, and on no account use on acetate rayons.) Wash to remove traces of dye.
	<i>White Silk and Wool:</i> Use a warm solution of oxalic acid or salts of lemon ( $\frac{1}{2}$ teaspoonful to $\frac{1}{2}$ pint) in place of chlorine bleach. Remember that these chemicals are poisonous.	Nicotine	Sponge with methylated spirits. (Test rayons.)
	<i>Coloured and Delicate Fabrics:</i> Treat first with a solution of potassium permanganate ( $\frac{1}{2}$ teaspoonful to $\frac{1}{2}$ pint water), applied immediately over the mark. After a few minutes rinse away with cold water.	Paint:	
	The remaining brown stain should be removed by treating with a solution of hydrogen peroxide (20 vol. diluted 1 part to 5 parts water), acidified with $\frac{1}{2}$ teaspoonful of vinegar. Rinse well.	Enamel	Treat with turpentine or white spirit.
Red ink	<i>Washable Materials</i> should be soaked in warm water to which a liberal amount of borax has been added. Wash and rinse, then bleach any remaining stain with solution of hydrogen peroxide.	Cellulose	Treat with acetone or amyl acetate. (Test rayons first.)
	<i>Unwashable Materials</i> should be sponged with methylated spirits. (Test Rayons.)	Oil paint	Treat with turpentine or benzene.
Green ink	<i>Washable Materials</i> should be washed in warm soapy water and treated with a strong solution of household ammonia. Rinse well. This treatment is not suitable for woollen or delicate fabrics.	Paraffin	Treat with cleaning benzene.
Marking ink	Most types contain aniline dye and are very resistant; repeated treatment with permanganate solution followed by oxalic acid solution ( $\frac{1}{2}$ teaspoonful to $\frac{1}{2}$ pint water) is generally effective (see "Writing Ink").	Rust	Treat as for iron mould.
Indian ink	Very resistant stain; a solution of citric acid is sometimes effective.	Scorch	Wash with soapy water containing borax, then gently rub in a little glycerine and wash again. A mild oxidising agent such as hydrogen peroxide is helpful, but there is no remedy for bad scorch marks.
Copying ink	Rub oleic acid into stain and leave for 15 minutes, then dip in ammonia solution, rub well and rinse.	Sealing wax	Sponge with methylated spirits.
Ball-point-pen ink	Sponge with methylated spirit. (Test rayons before treatment.)	Shoe polish	Sponge with methylated spirits or wash in warm water to which a little ammonia has been added.
Iodine	Treat with solution of washing soda or a solution of photographic "hypo." (1 tablespoonful to $\frac{1}{2}$ pint water.)	Soot	Treat with carbon tetrachloride.
Iron mould	Treat with a warm solution of oxalic acid or salts of lemon ( $\frac{1}{2}$ teaspoonful to $\frac{1}{2}$ pint). After a few minutes, rinse thoroughly. Handle acids carefully.	Tar	Scrape off tar and treat immediately with benzol or eucalyptus oil.
Mildew	Treat alternately with potassium permanganate solution and oxalic acid (see Writing Ink). These marks are very resistant, and short repeated treatments are necessary.	Tea	<i>White Materials:</i> Stretch the stained area over a basin, damp, and sprinkle with borax. Pour through hot water from a kettle. Push the stained area into the solution and leave to cool. Rinse, wash, and finish in usual way.  <i>Coloured Materials:</i> Sponge with a warm solution of borax ( $\frac{1}{2}$ oz. to $\frac{1}{2}$ pint). Rinse well.
		Transfers	Sponge with methylated spirits. (Test rayons first.)
		Varnish	Sponge with methylated spirits. If this fails, try turpentine or white spirit.
		Whitewash	Sponge with vinegar and water.
		Wine	Treat as for fruit stains.

# Gardening

By RICHARD SUDELL, F.I.L.A. (Garden Editor: "Ideal Home and Gardening")

## I. FLOWER CULTIVATION

**General Hints.**—Soil for flowers should be well tilled, not sour or pest-ridden, and should contain plenty of phosphates, since these make for early flowering. Bone-meal is a safe fertiliser to use in all parts of the flower garden, particularly where flowers are wanted in partial shade.

For seasonal bedding, ground should be dug in autumn and planted with bulbs and spring-flowering biennials. It should be dug over again, with a bone-meal dressing worked into the top spit, in late spring after the bulbs have flowered, and replanted with tender summer flowers at the end of May, or with hardier annuals, etc., if replanting is done earlier.

Perennial flowers in mixed or herbaceous borders should mostly be lifted once in three years, divided if over-grown, and replanted after the soil has been well dug and manured. Certain flowers such as peonies, madonna lilies, and oriental poppies have fleshy roots which resent disturbance. These are better not lifted, or only lifted once in six years if they become overcrowded, but they can be increased by division. Peonies, for instance, can have pieces taken off in September, with roots attached to each portion, the main plant being left undisturbed.

*Bulbs*, whether autumn or spring planted, are best set with the base of each on sandy soil. If planting in stiff clay, put a handful of sand in each hole that is prepared for the bulb. Or cover the whole bed with a layer of sand before planting, when some sand will fall into each hole automatically as it is made by the trowel. Depth rule is to cover each bulb with twice its own depth of soil. Bulbs that will grow rather tall, such as tall tulips, lilies, gladioli, and narcissi may advantageously be set even more deeply, so as to avoid wind damage.

*Annuals* are flowers which bloom profusely the first season and are then discarded. They may be sown in spring or autumn. Hardy annuals are better sown in late August or September. More tender annuals must be sown under glass in the early months of the year, or, if sown in autumn, they must be wintered in frames. These are planted out only when danger of frost damage is past.

*Biennials* are like annuals in that they flower once profusely and are then discarded, but biennials always take two seasons to reach flowering stage. They are mostly sown in April or May for the following year, in the open unless they are tender. Seedlings are thinned out, and in autumn transplanted to flowering quarters.

**Acacia (Mimosa).**—Tender shrubs, generally only suitable for greenhouse culture. All with yellow flowers, in the early months of the year. Sow seeds as soon as ripe, or take cuttings of half-matured wood in July or August. Feed well with weekly doses of liquid manure when growth is active.

**Acer (Maple).**—Hardy deciduous trees with ornamental foliage. The Norway maple, *A. platanoides*, is the best for difficult gardens. Japanese maples are smaller and very decorative, but rather more particular over soil, which should be light and rich. Slight shade prevents leaf scorch. *A. palmatum atropurpureum* is the red-leaved Japanese maple. Seed, layering, and budding are common methods of propagation.

**Achillea (Yarrow).**—Hardy perennials, mostly 2-4 ft., but some suitable for the rock garden. *A. ptarmica*, "The Pearl," is useful for cutting, and carries masses of small white double flowers. Other herbaceous-border types have flat heads of yellow or crimson. *A. tomentosa* is a rockery species 6-9 in. with yellow flowers. Increase by division of roots.

**Aconitum (Monkshood).**—Hardy perennial. Poisonous. Fleshy rooted (handle carefully as it contains poison), mostly blue flowered, July to September. 5 ft. Suitable for the back of the border or for a wild garden, in full sun or partial shade. Increase from seed sown in summer, or from root division in autumn.

**Adiantum (Maidenhair Fern).**—There is a hardy Maidenhair—*A. pedatum*—but most of the Maidenhairs need a winter temperature of about 60° F., with some shade and plenty of moisture, but no waterlogging of the soil. The hardy species likes similar conditions but needs less heat, and will grow in favoured gardens in the open. Increase usually by division.

**Agapanthus (African Lily).**—Blue or white flowering, particularly suited to tub culture. Loam with leaf-mould and well-rotted manure, and enough sand to allow free drainage are needed

**STAKING IS AN ART.**—The spikes of delphiniums, for example, should be tied up separately, not bunched together, as shown above. Left, wrong; right, correct.

for the compost. Pot in March, water and use liquid manure in summer, but keep dry and well protected from frost in winter. Increase by seed in March or by root division.

**Ageratum (Floss Flower).**—Sold in quantity in spring for border edgings. Half-hardy annual, of which there are several varieties with mauve, pink, bluish, or white flowers. Raise annually from seeds sown in heat early in the year. 6 in.

**Allanthus (Tree of Heaven).**—A large tree when mature, but can be grown in a mixed shrubbery with good effect if cut down each winter almost to ground level. Propagate by root cuttings in a frame.

**Asuga (Bugle).**—Dwarf plants, some of which have variegated leaves and blue flowers, in spring and summer. Suitable for rockeries. Propagate by division in March. 6 in.

**Allium (Onions).**—Several species are cultivated for their floral charm. They are treated like other bulbs, and may be grown in pots if desired. Pot in October. Colours: yellow, blue, white, lilac rose. Height from 12 to 18 in.

**Alstroemeria (Peruvian Lily).**—Tuberous-rooted perennials suitable for sunny borders and preferably grown in sandy, leafy soil. *A. aurantiaca* has orange-red flowers, and modern varieties have a wider range of colours. All suitable for cutting. Sow seeds in heat in January and plant out in May or June. Do not disturb the tubers, but mulch to protect from winter frosts.

**Althaea.**—See Hollyhock.

**Alyssum.**—Dwarf annuals and perennials for sunny beds and rock gardens. *Alyssum saxatile* is the golden alyssum of spring, and is increased by seed, or by cuttings taken after the flowers fade. *A. maritimum* is the white-flowered scented annual; there are also mauve varieties of this. Seeds may be sown under glass for early blooming, or in the open if glass cannot be used.

**Amaranthus (Love-Lies-Bleeding).**—Half-hardy annuals, best raised from seed sown under glass in early spring. Suitable for beds, borders, tubs, or vases, or for pots in the greenhouse. Flowers are graceful and drooping, and usually red. Height 10-40 in.

**Amaryllis (Belladonna Lily).**—These bulbs succeed best in a warm border under the greenhouse wall, outside, but they can also be grown in pots if the bulb is covered right up to the neck at the time of planting, in summer. The flowers are produced in August and September, and the foliage later. Height up to 3 ft. White to reddish purple. Bulbs must be protected from frost during winter, and fibre is useful material for this purpose. Give plenty of water while the flowers are opening.

**Anagallis (Pimpernel).**—Hardy annuals useful for front of border or for rockery pockets. Various colours. 3 in.

**Anchusa (Alkanet).**—*Anchusa italica* is a deep tap-rooted perennial, which sends up 5 ft. spikes that carry masses of blue flowers on their branches. June to August. "Dropmore" is the gentian blue variety, "Opal" has sky-blue flowers. Propagate by root cuttings in early spring. Plant in groups, allowing 18 in. from plant to plant. Well-drained and well-manured soil is best.

**Anemone (Wind-flowers).**—Hardy fibrous-rooted perennials such as *Anemone japonica* and its varieties, all with pink or white flowers from August to October, 3 ft.; or tuberous-rooted perennials that mostly flower in May if they are planted in October. These include the well-known Caen anemones and their double-flowered counterparts the St. Brigid anemones, which have such a wonderful blue, scarlet, maroon, pink, white colour range. Also many species that are suitable for the rock-garden, and some that flower in winter, such as *Anemone apennina* and *A. blanda*. Colours very varied, height mostly under 12 in.

**Antennaria (Chamomile).**—Hardy perennials, for a border in full sun. "Perry's Variety" of *A. tinctoria*, and the variety "Loddon" are specially fine in the late-summer border. A position in the foreground can be allotted to these plants as the foliage is silvery and attractive before the flowers come. Sandy loam is best, but they will thrive almost anywhere in sunshine. Height 2-3 ft. Yellow. Increase by division.

**Anthericum liliago (St. Bernard's Lily).**—Hardy tuberous-rooted perennials, suitable for the front of a border in light soil and full sunshine. Plant 9 in. apart in groups. Water during dry spells, and dress annually with humus. Pro-

pagate by division in October. White flowers in July and August. 18 in. Leave undisturbed as long as possible.

**Antirrhinum (Snapdragon).**—Summer bedding plants, perennial but usually grown as annuals, and probably best so treated, as older plants are more susceptible to the rust disease which has proved very troublesome of late years. They prefer dry, well-drained loam in full sun. Sow seeds in gentle heat in February, or sow in summer for the following season. Frame protection is not needed in normal winters. A very large number of good varieties are listed in catalogues, and these come true to colour and type, so that excellent colour schemes can be worked out using antirrhinums alone or with other subjects. Dwarf types 6-15 in., others up to 30 in., in all colours except blue. Antirrhinums should be "stopped" to encourage bushy growth; they will flower continuously from the first blooms until cut down by frost.

**Aponogeton distachyon (Cape Water Hawthorn).**—Continuous-flowering plant for pools of any size. It floats its leaves on the water surface, and sends up stems with fragrant white flowers with purple anthers, just above the water. The root is bulbous and is planted in the loam at the bottom of the pool, usually in a weighted basket. Slowly moving water suits it admirably. Propagate by means of offsets in March.

**Aquilegia (Columbine).**—The wild form, known as "Granny-caps," has very frilly petals and short spurs. Modern varieties such as "Crimson Star" have long spurs and much larger, showier flowers of different colours. Sow in spring for the following year, when the plants will flower from May to July. Plant out in flowering quarters in autumn, in groups, with 9 in. from plant to plant. The foliage is decorative, but apt to become a little untidy in late summer, when other plants should be grown near to disguise it. Height 1-2 ft.

**Arabis (Rock Cress).**—White- or pink-flowered dwarf plants that make a smother growth over rocks and banks. Single- and double-flowered kinds are obtainable, and all make a brave show in May and June. Increase by division or cuttings. 6 in.

**Araucaria.**—The well-known Monkey Puzzle tree is of this genus, and though large for most gardens, it is fine as a lawn specimen in larger parks. *Araucaria excelsa* is usually grown as a pot plant, and is distinguished by its candelabra-like growth of green stems with tiny spiny-looking leaves. Plenty of water is needed through the summer, and the plant should be kept well away from draughts at all seasons. This *araucaria* is called the "Norfolk Island Pine" and is one of the best of all pot plants for ordinary room culture.

**Arbutus (Strawberry Tree).**—A flowering and fruiting shrub or tree, with clustered cup-shaped blossoms, followed by orange-red strawberry fruits. It succeeds in peaty loam, and can be raised from seed or propagated by layering.

**Arctotis grandis.**—Half-hardy annuals, suitable for sheltered beds and borders in sun. Pearl-grey daisy-flowers in summer. 2 ft.

**Armeria (Thrift).**—Hardy perennials of cushion growth, smothered in spring with pink or red flowers. Suitable for border edges and for rock gardens. Dry loam suits them and sunshine is essential. 4-18 in.

**Artemisia (Wormwood or Old Man).**—Hardy shrubs or herbaceous perennials. *A. abrotanum* is the well-known Lad's Love. *A. lactiflora* is the best of the herbaceous species for the border and has creamy white flowers in summer. 5 ft. *A. stellariana* is the "Dusty Miller" with ornamental grey foliage. 2 ft. All do quite well in partial shade and ordinary well-drained soil. Tall varieties may be staked with pea-sticks. Propagate herbaceous types by division in spring, shrubs by cuttings in summer.

**Arum Lily.**—See *Richardia*.

**Asperula (Woodruff).**—Useful hardy annuals because they will grow in partial shade. *A. azurea* has blue flowers and is sweetly scented.

**Asphodelus luteus.**—Hardy perennials with grass-like foliage and tapering spikes of yellow flowers. June and July. 3 ft. Increase by division.

**Aspidistra.**—The well-known Parlour Palm. Useful because it is not affected by gas fumes, and will grow in the shade. Water sparingly, sponge the leaves occasionally to get rid of dust. If

necessary, repot, in March, when suckers may be removed to form fresh plants. *Aspidistras* flower near the soil level, and the inconspicuous blooms are frequently overlooked by cultivators.

**Aster (Michaelmas Daisies).**—Hardy perennials that will flourish in almost every soil and situation, though the best flowers are produced in full sunshine. Good soil makes a great difference to the size and quality of the flowers, especially of the taller types, and overcrowding must be avoided. Lift the plants every other year, at any convenient time between flowering and spring, when there is no frost in the ground. Replant only plump outer portions of root, and when these send up stems in the second season, reduce the number, so that every stem has ample space for growth. The types of aster vary. The *Amellus* group is early flowering, and the flowers are very large—like single China Asters. This group is best not planted until March. *Novæ-angliæ* and *Novæ-belgiæ* asters are available in great variety in catalogues and include flowers of bright pink, purple, wine, white, and mauve. A hybrid between ordinary Michaelmas daisies and *Solidago* (Golden rod) is available as *Aster luteus*, and this has masses of starry yellow flowers. Used to contrast with a collection of asters of the mauve-pink colour range this yellow-flowered hybrid is particularly effective. There are also dwarfs, *cordifolius*, *ericoides*, and *cordibeglii* sections of the genus (*Luteus* belongs to the last named).

**Aster, China.**—See *Callistephus*.

**Astilbe (Goat's Beard).**—Closely related to the *Spiræas*, with large panicles of flowers that are greatly valued in the mixed border. Moist soil enriched with cow manure or other organic matter is preferred, and a position by the waterside is very appropriate. May to September. White, pink, and crimson, 2-6 ft. Propagate by division of the roots in spring or autumn, and leave the plants undisturbed for three or four years.

**Aubretia (Rock Cress).**—Evergreen, trailing or carpeting plants about 4 in. high, smothered in spring with flowers of mauve, purple, violet, or rose, according to variety. Rich sandy loam and leaf-mould give the best results. *Aubretia* can be grown in pockets of walls, on rock gardens and as border edgings. Plant in spring or autumn, and increase by division or from seed.

**Aucuba japonica.**—Hardy evergreen shrub with spotted green leaves (Spotted Laurel) and, on female plants, scarlet berries. Useful to grow in full shade, but less satisfactory in full sunshine. Plant in March or October. Cut back weak stems in May. Propagate by cuttings which can be rooted in the open in autumn, or sow seeds from ripe berries. To produce berries at least one male-flowered bush must be planted near the others. Small plants in pots are useful for window-ledges in towns, and tub plants are ideal for sunless, paved, back yards.

**Auricula (Primula auricula).**—Show auriculas are grown in pots, and classed according to the colour of the petal edges, white-edged, green-edged, grey-edged, and selfs. Alpine auriculas are harder and will succeed in beds and borders and on rock-gardens. There are both single and double types of these. Raise show types from seed sown in the early months of the year, in pans of good seed compost, or take offshoots from older plants in spring or August. Sow alpine in spring: lift, divide, and replant every third season after flowering. All grow about 6-9 in. high; colours vary enormously and may be very striking.

**Azalea.**—See *Rhododendron*.

**Balsam.**—See *Impatiens*.

**Bartonia aurea.**—Hardy annuals with bright butter-yellow flowers appearing from June to October. 15 in. Allow 18 in. from plant to plant after thinning, to get the best results.

**Begonia.**—Perennials with fibrous or tuberous roots, somewhat tender and suitable for summer bedding, for baskets and window boxes or for greenhouse cultivation. Some have colourful flowers: others are grown chiefly for the beauty of their variegated foliage. Seeds of all kinds can be sown in January or February under glass, in very fine compost, slightly moistened, in a temperature of 65° F. Plants can also be raised by leaf cuttings—well-matured leaves laid on sand or fibre in a propagating frame. The undersides of the veins should be scored across with a sharp knife, and roots or bulbets will form at these

incisions. Small pieces of broken flower-pot laid on the leaf, or some other method, must be used to keep the leaf in close contact with the rooting medium. Warmth, moisture, shade, and plenty of leaf-mould and sand in the soil are the chief needs of all the begonias. Careful staking of the taller kinds is also needed, as the growths are exceptionally brittle.

**Bellis perennis** is the common field daisy, of which there are many garden varieties obtainable, some with fully double flowers of red, white, or pink. "Dresden China" is a particularly neat, small, but fully double pink-flowered type excellent in the crevices of crazy paving, or for cultivation on a rock-garden. 6-12 in. Propagate by seed sown in the open garden in June, or by root division after the plants have flowered.

**Bellium minus.**—A 3-in. daisy-like perennial flowering from July to September. Flowers purplish on the outside and white within. Suitable for the paved, rock, or sink garden. Plant in loam and leaf-mould in a sunny position. Sow in autumn or in March, under glass or divide roots in April.

**Berberis.**—Hardy shrubs, some deciduous and some evergreen. All with decorative berries, and many very suitable for hedges. *B. stenophylla*, smothered with flowers in April, is a spiny evergreen which stands up well to clipping (with secateurs in May and August) and makes an impenetrable hedge that will keep out dogs and children. It is one of the best of all hedge plants, but its roots spread widely through the soil, and so it is not suitable for tiny gardens. *Berberis Mahonia* and its varieties have striking evergreen foliage, scented yellow flowers, and purple berries, and do well under trees and on banks where it is difficult to grow many plants. *B. Wilsonæ* which has masses of coral berries is also excellent on banks, but needs sunshine to colour the berries. *B. Thunbergii* is a fine hedge subject, with purple foliage all summer. Many other varieties are listed in catalogues, and all can be planted in spring or autumn in ordinary well-drained soil. Propagate by sowing seeds when ripe, or by cuttings or layers in late summer.

**Bocconia (Plume Poppy).**—Hardy perennial for light, rich soil and sunny borders. Flowers are creamy coloured. Height 6-8 ft. June to October.

**Boronia.**—Evergreen shrubs with scented flowers. Suitable for pot culture in the greenhouse. Pot up in 6-in. pots for flowering. Feed with liquid manure as the flowers develop. Cut back after blooming, stand pots outside from June to September. Propagate by cuttings of young shoots in May, rooted in sand, peat, and charcoal. February to April. Red, yellow, or brownish purple. 1-2 ft.

**Bougainvillea.**—Tender shrubby climbers for greenhouse culture. Grow in pots of sandy soil. Cut back in February to near the base of the previous season's growth. Red, etc. June and July. Increase by cuttings of new growth, 3 in. long in April or May.

**Buddleia.**—Hardy shrubs, deciduous, useful where bold planting is needed. *B. variabilis*, the purple buddleia is best cut hard back in February. *Buddleia alternifolia* has a weeping habit and makes a fine lawn specimen: this should be pruned, if needed, after flowering. Increase by cuttings. Season of flowering and colour varies according to variety.

**Bupthalmum (Ox-eye).**—Hardy perennial. *B. salicifolium* is the species cultivated for its mass of golden yellow, daisy-like flowers produced continuously from June until September. 18 in. Propagate by division in spring or autumn. Ordinary soil is suitable.

**Buxus sempervirens (the Common Box).**—Light, well-drained soil is best. Clip in May and August. Propagate by cuttings in August or September, by division in March or September and by layering in autumn. Varieties with golden or silvery foliage are obtainable. *B. suffruticosa* is the dwarf type used for border edgings.

**Cactus.**—Cacti are none of them really hardy in this country, though some are grown in rock-gardens and covered with glass and other protection in winter. All are suitable for moderately heated greenhouses, or they can be grown as room plants. Most will stand up to culture in modern central-heated rooms, where ferns and other

flowering plants do not thrive. Water during the summer, when flowers are developing, and dryness through the winter, when flowers are absent, is the general rule, but winter blooming epiphyllums must, naturally, not be allowed to become too dry at any season. Plenty of sun, and a soil composed chiefly of crushed brick or flower-pot, mortar rubble, and burnt earth from beneath the bonfire are secrets of success with the cereus, mammillaria, and echinocactus group. Epiphyllums, phyllocacti, and rhipsalis may have a little peat added to the compost. Where small cactus gardens are made, some charcoal in the bottom layer of compost will help to keep the soil sweet for a long period. Many inexperienced cactus growers are unaware that these plants should, mostly, flower regularly each year. If they do not, they have probably been overwatered, had too little sunshine, or been too well fed with nitrogenous food. Cactus cuttings root very readily: leave pieces that break off, or have been cut off, to dry for a couple of days before inserting them in sandy moist soil or pure sand, under a glass, or uncovered if the moisture supply can be kept up without being given too freely. Summer is the best time to root cuttings. Choice cacti are also grafted on to other strong-growing plants in March, and in some cases offsets are freely available to form new plants.

**Calceolaria** (Slipper flower).—Tender and hardy herbaceous perennials and slightly tender shrubs. Large-flowered tender herbaceous types are sown under glass in June, potted into 4-in. pots in September, and later into 7-in. pots for flowering in the greenhouse. Hardy herbaceous calceolarias are grown in the rock-garden. Seed is sown under glass in March, roots divided in spring, or cuttings taken in autumn. Shrubby calceolarias are the kind used for summer bedding. Cuttings of these may be inserted in a frame in September, or they may be inserted in a shallow depression in the garden, in sandy soil, and covered with a sheet of glass at ground level for the winter. These outdoor cuttings usually produce good strong plants for the following summer display. Many varieties are listed in catalogues. Shrubby kinds will grow to 4 ft., but normally plants do not exceed 1 ft. when grown for bedding.

**Calliopsis**.—Annual plants of the coreopsis family. Mostly with yellow and chocolate-maroon flowers. Very useful for edgings, though some grow to as much as 18 in. Sow outdoors in spring, where the plants are to bloom.

**Calendula** (Pot Marigold).—Sow outdoors in August, for the best results. Or sow in spring for late-summer displays. Modern varieties include full doubles such as Orange King, lemon-coloured varieties, and some with quilled petals. Seedlings can be transplanted or grown on where sown, but 1 ft. should be allowed between the plants, which will usually grow to a height of 18 in. if soil is congenial.

**Callistephus** (China Asters).—Half-hardy annuals flowering in late summer and autumn. Single varieties are especially useful as cut flowers in the home. Many different types—peony-flowered, branching double or single, quilled, and so on, in numerous colours, are obtainable from seedmen. Sow under glass in February, or sow in the open in May and pot up the plants for flowering late under glass. Do not bring into the greenhouse until the buds begin to show colour.

**Calluna vulgaris** (Ling or Heather).—Hardy evergreen, suitable only for full sun and sandy peaty soil. Plant in spring or autumn. Trim off dead flowers in April. Propagate by cuttings inserted in "heather" soil (sandy peat) in a frame, or increase by layering, in summer. Many white and pink varieties are available, some with double flowers. 18 in.

**Caltha** (Marsh Marigold).—Hardy perennials for the waterside. Plant in full sun or partial shade, but in moist soil. Propagate by division in March or July. *C. palustris* is most common, and is the Kingcup of the streamside. A double form is available that lasts a long time in the water-garden.

**Camellia**.—Half-hardy, evergreen shrubs for greenhouse culture or very sheltered positions in warm districts. Pot up in May in loam, leaf-mould, and sand. Harden off, stand outside in summer, and return to the greenhouse in

September. Propagate by grafting on *C. japonica* in spring or take cuttings in late summer. There are many varieties in a range of red-to-white colours, flowering from February to May.

**Campanula** (Bellflowers).—Hardy annuals, biennials, and perennials. Some are slightly tender and do best in the cold greenhouse. They include tall subjects and dwarfs for the border edgings or rock-garden. Some of the most useful are *C. pyramidalis* (4-6 ft.) the Chimney Bellflower, for greenhouse pots; *C. isophylla* and *C. Mayi* for hanging baskets; *C. medium* the well-known Canterbury Bell (biennial), *C. carpatica* for bedding, *C. persica* (2 ft.) for the mixed border. Culture: the ordinary procedure for the type. Soil preferably sandy loam with some leaf-mould, but border campanulas and Canterbury Bells will grow almost anywhere. Canterbury Bells should be sown as early as possible in the year, as only well-grown plants will flower the following season. Small plants sometimes wait until the third year before flowering. All campanulas belong to the white-blue-purple colour range.

**Canary Creeper**.—See *Tropaeolum*.

**Candytuft**.—Hardy annual and perennial plants with white, crimson, lilac, or purple flowers. Perennial white-flowered candytuft—*Iberis sempervirens*—is a favourite for rock-gardens and walls. Propagate all kinds from seed; perennials also from division or cuttings. 1 ft.

**Canna**.—Tropical plant with ornamental leaves and scarlet or yellow flowers. Raise from seed in February. Soak the seed in warm water for a day, then sow in good compost and keep in a temperature of 75° F. until it has germinated. Pot up in March or April, and for outdoor displays plant out in June. Repot plants and winter them under glass from September onwards. Keep them moderately dry, until the stems die back: water and restart into growth like dahlias in the New Year.

**Canterbury Bells**.—See *Campanula*.

**Carnation**.—See *Dianthus*.

**Carpentaria californica** (Californian Mock Orange).—Shrub for a sheltered position, such as against a south wall. Plant in autumn in well-drained soil. Propagate by cuttings taken under glass in April, or by layering in September. White. 5-6 ft.

**Catananche**.—Hardy perennial. *C. coerulea* with blue flowers, and its variety with white flowers, are popular border plants. Raise from seed sown outdoors in summer, and transplanted in spring to flowering quarters. 20-30 in.

**Celosia** (Cockscomb).—Half-hardy annuals, very useful as pot plants for window or indoor decoration in summer. Sow in pans in March in rich seed compost, temperature 70° F. and cover with only a fine dust of soil. Transplant and pot up singly as soon as possible. Keep near the glass, repot as needed, and gradually harden off ready to plant out or stand on window ledges in June. Pots may also be grown throughout in the greenhouse. Warm, rather close, atmosphere is needed by the young plants, and when buds show, liquid manure can be given twice a week until the colour appears. *C. pyramidalis* has flowers of scarlet, crimson, or gold. 30 in.

**Centaurea**.—Hardy annuals, biennials, and perennials. *Centaurea cyanus* and *C. suaveolens* are the blue cornflower, and mauve or yellow sweet sultan, respectively. The cornflower is available also in rose, white, and purple. Both are best sown in August for the following summer, but sweet sultan is more likely than the cornflower to suffer frost damage, and in cold gardens it should be sown in spring, under glass, and transplanted to the open in May. *C. macrocephala* is a deep yellow, 4-5 ft. perennial cornflower which makes a good show in the border during July and August. *C. gymnocarpa* (The Dusty Miller) and *C. ragusina* are useful in greenhouse and summer borders for their ornamental foliage. These can be increased by cuttings in September, or raised from seed.

**Cheiranthus** (Wallflowers).—Hardy biennials and perennials. Some are suitable for the rock-garden. The most common in gardens are *C. Allioni*, bright orange, or lemon yellow, often used for formal bedding in conjunction with blue forget-me-nots and late-spring flowering bulbs; and *C. Cheiri* which is the well-known scented

wallflower and is available in numerous named varieties. Seeds should be sown in May to flower in the following year. It is best to sow them thinly in straight lines across the vegetable garden, where the hoe can be used between the rows to destroy weeds. Sown thinly they may need no transplanting until autumn, but overcrowding must be avoided, and it is common to transplant the seedling while still small, to allow 3 or 4 in. from plant to plant. In autumn when bulbs are being set out, these wallflowers may be used for interplanting, they will provide a mass of colour at less cost than if bulbs alone were used. Wallflowers will grow on for another season, but the first year's flowers are the best, and seed should be sown every year.

**Chimonanthus fragrans.**—Hardy winter-flowering shrub, with parchment and brown flowers that are heavily scented. A newer variety

are usually grown under glass from then onwards. After flowering these chrysanthemums are encouraged to make strong basal shoots, the top being cut down almost to ground level. Under glass these shoots appear in January and may be taken off when four or five good leaves have developed. They are inserted as cuttings in sandy soil in a propagating pit, and when roots have formed each is potted up into a separate pot, about April. In May they need larger pots, and the central growth is stopped, to encourage bushiness. The final potting is done in June or July, then stand in the open until September, when they will be brought on to the sunny shelves of the cool greenhouse. Removal of some of the flower buds, leaving only the most promising on each stem, results in fine specimen flowers, but a spray of flowers is preferable in many cases, particularly on those varieties that flower early

THE METHOD OF STOPPING AND DISBUDDING CHRYSANTHEMUMS is shown in three stages: (1) the top is pinched out; (2) side shoots are pinched out; (3) side buds are removed.

with brighter coloured flowers of golden yellow is more showy but much less fragrant than this species. Plant in October or March and train against a warm wall. Cut back side shoots to within five or six eyes from the main stem, after the flowers fade. Increase by seeds, suckers, or by layering in August.

**Chionodoxa.**—Hardy spring-flowering bulbs. Plant in full sun or in shade, in October, 2-3 in. deep and 4 in. apart. Do not disturb after planting until the growths become overcrowded. Excellent for rocky pockets and for edgings. Blue, mauve, or white. 9 in.

**Choisya ternata (Mexican Orange).**—Evergreen, near-hardy, shrub with clusters of star-like, scented, white flowers. Can be grown in the open in sheltered positions, such as against a house wall, May, 8-10 ft. Increase by layering. Prune straggly shoots only after flowering.

**Christmas Rosa.**—See *Helleborus*.

**Chrysanthemum.**—Hardy annuals and perennials. Annuals are sown outdoors in spring to flower during summer. They include the well-known yellow "Morning Star" and also the tricolour chrysanthemums. Among perennials are the large white daisies—*C. leucanthemum* (3 ft., June to October), *C. maximum* and its varieties with double and fringed flowers (July to September 14-3 ft.), and *C. uliginosum* (5 ft., September to October). Plant spring or autumn, lift and divide in spring in alternate years. Japanese chrysanthemums, sold by florists in autumn, are hardy enough to stand our summers, but top growth will die back in winter; even the roots do not always stand up to frosts. As many of these do not flower until after September, they

and are grown for border decoration. These early-flowering varieties may be lifted and wintered in cold frames after the tops are cut down, or they may be left in the open, with ash piled over the crowns to protect them. Division, and cuttings in spring are the most common methods of increasing the garden plants, but it is quite easy also to raise good plants from seed, sown in boxes in February, and treated just as half-hardy annuals are treated. Colours, heights, etc., vary greatly, and catalogues should be consulted.

**Cistus.**—Shrubs suitable for poor sandy soil in sunny gardens. The flowers last only from early morning until early afternoon, in many cases, but they are opened in great profusion and are very brightly coloured, rose, white, purple, mauve, etc. No regular pruning is needed. Increase by layering in August, seed in April, or cuttings in August.

**Clarkia.**—Hardy annuals with flowers of pink, purple, or white set close to the stem on tall spikes. 24 in. Sow in spring for border decoration, or sow in August in pots for the greenhouse shelves.

**Clematis.**—Hardy shrubs, mostly climbers, suitable for walls, screens, and pergolas. Light, well-drained, well-manured soil suits them, and care should be taken over pruning, as different varieties need different treatment. The late-flowering group, including the common purple clematis, should be cut back hard in February, as flowers come on the young wood only. Some types flower on both old and young wood. Some flower quite early in the season on wood of the previous year's growth. Nurserymen will always give advice on this at the time of purchase, and it is best to seek this, as many different hybrids are

now on the market, and differences in habit of growth occur even within the groups.

**Colchicum.**—See **Crocus**.

**Coleus.**—Ornamental-foliaged plants for greenhouse culture. They can also be used for summer bedding. Sow in heat in March or propagate from cuttings at any time when these are available. Syringe frequently in warm weather, and use liquid manure. Keep temperature above 50° F.

**Columbine.**—See **Aquilegia**.

**Convallaria (Lily of the Valley).**—Hardy perennials that will grow in partial shade, in good rich soil. Plant in October, covering the crowns with a 2-in. layer of leafy soil. Lift about once in four or five years, when the clumps begin to get crowded. Increase by division.

**Coreopsis.**—Hardy perennials. (Annual *Coreopsis* is known as *Calliopis* in catalogues). Any ordinary garden soil is suitable, and plants can easily be raised from seed sown outdoors in April. It pays to raise fresh stock fairly frequently. Transplant seedlings 9 in. apart. Single and double varieties are obtainable, all bright yellow, and excellent for cutting. 2-3 ft.

**Cornflower.**—See **Centaurea**.

**Cosmos.**—Half-hardy annuals with pink, white, yellow, and crimson flowers superficially like single dahlias, and with feathery foliage. Sow under glass in February, and do not move the seedlings from the box in which they are pricked out until the first sign of the flower is seen. They will flower continuously through summer, but if planted out too soon, they often make too much growth and too few flowers. 2 ft. upwards.

**Cotoneaster.**—Hardy shrubs with bright berries, very good on poor chalky soil. No regular pruning is needed: Plant in autumn or spring. Height varies according to species. *C. horizontalis* is the flattened-growth form suitable for planting against walls.

**Crocus.**—Hardy perennial of which the root is a corm, though commonly referred to as a bulb. Plant in autumn, 3 in. deep and 4 in. apart. Lift and divide every fourth or fifth year, when the foliage is absent. Crocuses can be grown in pots or in bowls of fibre, but must be kept quite cool until the petals show colour, when they may be brought into the sunny window of a living-room. Some species of crocus suitable for rock-garden culture flower in autumn. The so-called autumn crocus is actually *Colchicum autumnale* (Naked Ladies). This can be planted in August, and will flower almost at once, sending up foliage only after the flowers have died away.

**Cuttings.** The principles of this method of plant propagation may be summed up in a few words, though the varying requirements of different plants make the subject almost inexhaustible. Cuttings are pieces of a plant that are cut off, and then induced to develop roots, etc., and so become new whole plants. They are, when mature, the exact counterpart of the old plant, in colour, size, habit of growth, and so on. In this they are superior to seedlings which may have inherited characteristics from the plant which produced the seed, and also from some other plant, which may or may not be known to the gardener. Seedlings are therefore very likely to vary considerably from one another as well as from the plant that gave the seed. Cuttings are of many kinds. They may be soft-growth cuttings, i.e., pieces of new soft growth that is still immature; or half-ripe cuttings, i.e., pieces of new growth from the current year's stems, but becoming ripe or woody; or well-matured ripe wood. Soft cuttings are the most difficult to root, for the tendency is for the cutting to become limp and decay before roots form. Such cuttings must be kept in a close moist atmosphere, and are usually placed under a bell glass or in a special propagating frame. Harder cuttings will root in the open in late summer when the soil and air are warm and mists are frequent. Hard-wood cuttings taken in November will stand through the winter in the garden, and in spring when growth commences they will form a good root system. These cuttings are not ready for permanent quarters until the following autumn. All such cuttings need open soil in which there is some coarse sand: otherwise there is not sufficient air in the soil, and the cutting may decay. It is also essential that the moisture supply should be kept up. Other cuttings that can be rooted include leaf

cuttings (see *Begonia*) and root cuttings (see *Papaver*). The use of special chemicals for rooting cuttings is a development of modern horticulture. See Section V.

**Cyclamen.**—*C. persicum* is the well-known butterfly flower sold in pots at Christmas time. Dormant corms are potted in August, or seeds are sown in early spring or in the previous autumn in gentle heat. The secrets of success are moist steady heat when starting the corms into active growth, no draughts, careful watering and allowing the corms to become almost dry between Easter and August. A plant in a pot may be kept for many years with care, but it is never quite so floriferous after the second season. Colours various, 10 in.

**Cytisus (Broom).**—Hardy shrubs that like warm, dry soil and sunshine. Plant in October. Cut back all the young wood by one-third or one-half after flowering, but do not cut into old wood. New plants can be raised from seed sown out of doors in September or under glass in March. It is also possible to take cuttings in March or August.

**Daffodils.**—See **Narcissus**.

**Dahlia.**—Half-hardy perennials with tuberous roots. They can be raised from seed, treated in the normal way for half-hardy annuals. At the end of the season, tubers will have formed on the roots (if culture has been good), and these can be lifted and stored away from frost. In early spring, (January to March) tubers should be placed in boxes of moist soil on a greenhouse shelf, and when young growths appear, these must be taken off as cuttings, and potted singly in small pots to form roots. Pot on as required, and plant out at the end of May, when danger of frost is past. Colours and types vary enormously, and catalogues should be consulted.

**Delphinium.**—Hardy annuals and perennials. Annuals are generally known as Larkspur, and include pink, purple, and blue-flowered varieties, 18 in. to 2 ft. Perennial delphiniums are subjects which have received much attention from hybridists and cultivators, and giant stems of spectacular flowers in all shades of blue, purple, white, and pink are now offered by nurserymen. Plenty of lime and plenty of humus in the soil are needed for good cultivation. Plant in early September or in late February or March: the roots are fleshy and inclined to suffer from disturbance in mid-winter. A pile of ash over newly planted crowns is useful in the first winter, and may be repeated each year. Thin out growths to allow for good development—well-grown plants need to be spaced 4 ft. apart, but the usual distance in 18 in. apart in groups of three, in the mixed border. *Belladonna* delphiniums are dwarf, and may be set 1 ft. apart. Increase by taking cuttings of the best of the spring growth, when they are 3 in. high, or raise new varieties from seed. When the flowers fade, cut back stems to within a foot of the ground: a second crop of bloom will result.

**Dianthus.**—The plant family that includes pinks, carnations, and sweet williams. All grow best in full sunshine, and prefer a well-drained soil with some mortar rubble worked into it during digging. Lime is essential for pinks and carnations.

**Carnations** are of several kinds. There is the old hardy border carnation, which flowers in July. This is the flower of the cottage gardens, and needs only to be grown in sun and suitable soil, and propagated every other season by layering, or by cuttings if preferred. Layering is so easy that it is generally better to adopt this method. A ring of prepared soil is placed round the old plant, to receive the "layers." Each side growth with no flowers is treated in turn. Two pairs of leaves are removed, at a distance about three inches from the tip of the growth. A slanting, upward cut is made through this part of the stem, in such a way that the stem can be bent down into the prepared soil, and pegged there, with the "tongue" open under the soil. Soil should be pressed firmly round each layer before it is left. In about four weeks the roots will have formed, and after about six weeks it will be possible to sever the plant from its parent. It is usual to layer about the end of July, and to move the rooted plant to its new quarters in October. If the garden is extremely cold, the new plants can be wintered in frames, but this should not be necessary with the hardy border carnation. In addition to this type there

are perpetual-flowering carnations, which are hybrids that continue to flower from spring until late autumn. These are a little less hardy than the border carnation, and in difficult gardens they should always be wintered in frames. Cuttings may be taken, or if the growth is suitable, layering may be practised. As some of these plants become rather tall, cuttings are often necessary, and the best type of cutting is a side growth from the middle portion of a tall flowering stem. Cuttings can be pulled out at a joint, and inserted in

- A. PARENT PLANT.
- B. NON FLOWERING SHOOT.
- C. NOTCH.
- D. CUT AWAY LOWER LEAVES.
- E. PEG.
- F. LEAF MOULD AND SAND.

**LAYERING CARNATIONS.**—A young non-flowering side shoot is pegged down into a low mound of fresh sandy soil. A few lower leaves are cut away, a notch is made below a joint before the shoot is pegged down. In six to eight weeks the layer can be severed from the parent, but it is left for a few weeks before transplanting.

sandy soil in a propagating frame. Malmaison carnations are suitable only for cultivation under glass, though very little heat is needed. Young layers or rooted cuttings are potted up singly in September—or at any suitable time, if all-the-year-round cultivation is practised. Steady growth, plenty of ventilation, and not too much heat are needed for success, and all the sunlight possible must be allowed.

**Pinks** are of many different types too. Some are dwarfs suitable for the rock-garden, some are particularly suitable as border edgings—the well-known double white “Mrs. Sinkins” pinks are an example—and some are tall enough to demand a place in mixed borders. Dianthus gardens include pincotees and many hybrid pinks, most of which are listed in catalogues. All need much the same cultural conditions as carnations, and all are readily increased by cuttings.

**Sweet williams** are grown as biennials, and many carnations and pinks, and the hybrid sweet wivelsfield, are also grown in this way, seed being sown outdoors in early summer for the following season. The Dianthus family has a very wide colour range, and catalogues should be consulted.

**Diervilla (Weigela).**—Hardy deciduous shrubs, useful in all soils, but flourishing specially in moist leafy loam. “Abel Carriere” variety has trumpet flowers of carmine with an orange-yellow throat. 7–9 ft. May and June.

**Digitalis (Foxglove).**—Biennials and perennials. *D. purpurea*, white and pinkish purple, is the common type. Sow seed in spring or early summer. Flowering from June to September. 1–4 ft.

**Dimorphotheca (Star of the Veldt).**—Half-hardy annual, best sown in April in light soil and a sunny position to flower in summer. Orange. 1 ft.

**Doronicum.**—Useful early-flowering perennials

with yellow daisy-flowers. Ordinary soil and a position in the sun suits them. Increase by division after the flowers have faded. 1 ft. to 18 in.

**Echeveria.**—Rosette-shaped succulent, much used for edging summer borders. Increase by offsets in summer. Pot these, and bring them under glass for the winter.

**Eranthis (Winter Aconite).**—Hardy, tuberous-rooted perennial. Plant in the autumn beneath shrubs and in sheltered corners. The bright-yellow flowers appear in January.

**Echinops (Globe Thistle).**—Hardy perennials for sunny borders in light loam. Plant in spring or autumn. Leave undisturbed as long as possible. *E. ritro* has attractive steely-blue globe flowers. 4 ft.

**Erica (Heathers).**—Various heaths will do well in gardens, but most species will not tolerate lime. Some that will succeed in ordinary limed soil are *E. carnea* and its varieties, *E. mediterranea*, and *E. terminalis*. Complete “Erica gardens,” comprising low dwarfs and carpet types and tall bushes and hedges, are a comparatively modern feature of gardens. Plant in October and where bushier growth is wanted trim back young growths in April.

**Erigeron.**—Hardy perennials with daisy-like flowers, mostly of mauve colouring. Plant in sunny borders in autumn. Increase by division.

**Eschscholtzia (Californian Poppy).**—Hardy annuals that prefer light soil in full sun. Sow preferably in August, or in March, and thin to allow 9 in. from plant to plant. Mostly bright yellow, 18 in.

**Forget-me-not.**—See *Myosotis*.

**Forsythia (Golden Bell Tree).**—Hardy deciduous shrubs, with masses of golden flowers on bare stems in early spring. Some are useful as hedge plants, others are more suitable to cascade over porches or over old trees. Plant in autumn. 6–10 ft. March and April. Increase by cuttings of current year’s wood taken in June or July, or layer stems in summer. Many forsythias layer themselves when the stems bend over to touch the ground.

**Freesia.**—Slightly tender bulbs, best for the cool greenhouse. Plant in August in pots of rich, sandy loam, 2 in. apart, 1 in. deep. Grow on without too much heat, to flower from January to April. Increase from seed or offsets. Various colours, but the old cream Freesia has the finest scent.

**Fritillaria.**—Hardy bulbs, suitable for any ordinary garden soil. *F. meleagris*, 6–10 in., is the small Snakeshead, which thrives in moist sandy loam, and *F. imperialis*, 30 in., the Crown Imperial. April to May.

**Fuchsia.**—Tender or half-hardy shrubs, deciduous, flowering normally in late summer. Many fuchsias are only suitable for indoor cultivation except in summer, when they are set out for summer bedding. *F. Riccartonii* is the near-hardy hedge plant (4 ft.). Cut back fuchsias in February, to encourage bushy young growth. Keep the water supply constant through the growing period. Pot fuchsias may be rested from the time the leaves drop until February. Take cuttings of fresh young growth (1 in.) and root them in pots of sandy soil in February or March, or take 3–4-in. cuttings of half-matured wood in August. Fuchsias may be trained as standards in the greenhouse, or grown in hanging baskets.

**Gaillardia (Blanket Flower).**—Annuals and perennials with red and yellow flowers from June to October. Sow annuals in spring and thin out to 1 ft. apart. Sow perennials in the open in May, and preferably treat them as biennials, sowing afresh each season. 1–2½ ft.

**Galanthus (Snowdrop).**—Hardy bulbs excellent for the shady parts of the garden. Plant in August, 3 in. deep and 3–4 in. apart. Lift only when the groups become crowded. There are single and double, short and tall varieties available.

**Gazania.**—Showy yellow and brown flowers suitable for summer bedding or to flower in pots indoors. Increase from basal cuttings in summer, inserted in sandy soil in a propagating frame. Protect from frost in winter and allow to rest after the flowers fade.

**Gentiana.**—Rock-plants that are mostly a rich blue, and greatly valued by the alpine gardener. Also some border perennials. Moist well-drained gritty loam is good for the alpine. Ordinary

border soil does for the willow gentian, *G. asclepiadea*, which has blue flowers in June to August and grows 18 in. high. Lime-free peat or leaf-mould is needed by *G. sino-ornata*, a late-summer bloomer useful for formal beds.

**Geranium.**—Hardy perennials with blue, pink, or white flowers, suitable for rock-gardens and borders, according to variety. Increase by seeds or division. (The popular bedding geranium is actually a *Pelargonium* (which see).)

**Geum.**—Hardy perennials useful in mixed borders. Varieties with scarlet and orange flowers are available. Raise from seed sown in the open in April or plant in spring or autumn and increase by division. April to October, 6 in. to 2 ft.

**Gladiolus.**—Plants that have recently received the attention of hybridists. Corms are now sold by the million for spring planting. Some are early flowering, and some flower only in late summer or autumn. Plant 4 in. deep with sand under each corm, and allow 6 in. between the corms. In most gardens stakes are needed, but deeper planting in light sandy loam may avoid the necessity for this. Propagate by seed or offsets. Lift the corms at the end of the season and clean them before storing: the offsets can be planted out in a sheltered part of the garden in March, to grow on and make flowering corms.

**Gloxinia.**—Useful subjects for pot culture in greenhouse or living-room. Start tubers in spring, in a box of moist rich soil. Pot up and grow on without a check, and dry off again after flowering. Increase by seed sown under glass in January. Various colours, June to October.

**Godetia.**—Hardy annuals which prefer moist soil, but need sunshine. Sow in spring and thin out to 9 in. apart. Pink, mauve, etc. 1 ft.

**Grass Surfaces.**—For large lawn areas or for garden paths, grass is best sown on a well-dug, rolled, and raked site. Turf can be laid, but the best turf is costly, and inferior turf not worth buying.

Soil can be prepared for September sowing, which is ideal, or for spring sowing, which is a good second best. Actually seed may be sown later than September if the weather remains good, but sown too late it is apt to decay instead of germinating.

Allow 2 oz. of good seed per sq. yd. if possible.

**How to Sow a Lawn.**—Divide the seed into two portions; half is sown in one direction, 1 oz. per sq. yd., and half in the other direction, 1 oz. per sq. yd. Seed is lightly raked in and covered with a thin dusting of fine soil.

A smaller quantity will take longer to produce a good lawn. Divide the seed into half, then divide it into portions to correspond with the length of the lawn, allowing 1 oz. to each yard of lawn length. Sow a yard strip at a time, with a separate portion of the seed (i.e., 1 oz. to the yard). Then divide the other half of the seed into portions according to the width of the lawn, and again sow yard strips of the lawn, widthways. Sowing in two directions in this manner ensures even distribution of the seed.

Roll lightly after sowing, and cover with a little extra fine soil if necessary. Protect from birds by stretching black cotton between sticks a few inches above the ground level. This will discourage the birds by catching in their wings.

Roll when the grass is an inch or two high.

Then, on a dry day, use the mower with the blades set high. Roll and mow alternately after this until a good thick growth is obtained. Sulphate of ammonia mixed with sand or fine soil is the best stimulant if one is needed, but only very small quantities (not more than  $\frac{1}{4}$  oz. of sulphate at a time to each sq. yd.) should be used, and this only once in three weeks during early summer.

**Gypsophila.**—Hardy annuals and perennials for dry soil and full sun. Raise from seed in March. Increase perennials by division in spring or autumn. Pink or white, single or double. 4-10 in. according to species.

**Helenium.**—Hardy perennials that succeed in almost every garden in sunny borders. Plant in spring or autumn and increase by division. Yellow or bronze, 1-4 ft.

**GERANIUM CUTTINGS** are shown in four stages: A. Cutting with "heel" of old stem attached. B. Cutting, lower leaves removed, cut below a leaf joint. C. Roots begin forming but not ready for potting. D. Roots formed ready for potting into 3-in. pots.

**Helianthemum** (Sun Roses, or Rock Roses).—Dwarf evergreen perennials suitable for the rock-garden or water edges. Colours various. 1 ft. Plant in March or October. Increase from seed, or from cuttings under glass in August.

**Helianthus** (Sunflowers).—Hardy annuals and perennials. The large-flowered sunflower is a little tender and must either be sown under glass, or sown late enough to escape frosts. Perennial sunflowers are planted in spring or autumn and increased by division.

**Helichrysum** (Everlasting flowers).—Half-hardy annuals or perennials, for sunny positions in moist, rich loam, with good drainage. Sow annuals in spring under glass. Increase perennials by division in spring, or by cuttings in April. When the various coloured daisy flowers are almost (but not quite) fully open, cut them and hang them upside down, in small bunches, to dry for the winter.

**Heliotropium peruvianum** (Cherry Pie).—Summer bedding plants which can be raised from seed in spring, or from cuttings in autumn treated as advised for calceolarias. Purple, fragrant, May to September. 1-3 ft.

**Helleborus** (Christmas Rose).—Hardy perennial, suitable for partial shade, or for a greenhouse border or pots. Increase by division in February

or March, after the flowers fade, but do not divide into very small portions. Plants can be potted up in autumn for December flowering under glass, or they can be set out to make a late-winter display in a formal bed. *H. niger* is the white "Christmas Rose" which will flower in December and January in a frame, but is often not in flower in the garden until February. *H. orientalis* is the Lenten Rose, flowering from January to April, various colours. 1 ft.

**Hemerocallis (Day Lily).**—Perennials with rush-like foliage and yellow or reddish flowers that last for a day only. Increase by root division in spring. Ordinary soil and a position by the waterside or near the front of the mixed border suits them. 1-2 ft.

**Heuchera.**—Compact bushy plants with dainty flowers in sprays. Perennial. Divide plants in spring, or raise from seed. Plant 9 in. apart, in groups. 14-24 ft. Pink or red. June and July.

**Hippeastrum.**—Half-hardy bulbs for greenhouse, or for the warm border on the south of a greenhouse wall. Good rich loam, on the heavy side, with some charcoal and bone-meal is suitable. Repot, and propagate by offsets, or plant out in February. Colours various, winter or spring. 1 ft. to 18 in.

**Holly.**—See *Ilex*.

**Hollyhock (Althaea rosea).**—Perennial plants that are often, and better, treated as biennials as young plants are less subject to rust disease. Sow seed in early May in the open, and move to flowering quarters in autumn. Plants may also be raised from cuttings in summer. Colours various. 6-10 ft.

**Honesty.**—See *Lunaria*.

**Hyacinth.**—Bulbs excellent for pot culture and for gardens. Pot up from August to November, in soil or fibre. Plant out in the open garden in October. Small bulbs are sold for bedding and are quite satisfactory. Various colours, flower in the spring.

**Hyacinthus candicans (Cape Hyacinth).**—Good plants for well-manured sandy loam, and sunny borders, but they will also do reasonably well in partial shade. August. 2 ft. Plant in March or in October.

**Hypericum.**—Hardy shrubs, evergreen and deciduous, also annuals and perennials. *H. Moserianum* is one of the most useful, and is a perennial 1 ft. to 18 in. high, with bright golden-yellow flowers. This is useful in complete shade, under trees, etc. July to August.

**Ilex (Holly).**—Green and variegated varieties of this popular evergreen are obtainable. Most hollies are of one sex only—at least one male and one female plant are needed for berries to ripen. Holly makes a fine hedge, and plants can be raised from seed for this purpose. Pack the berries into moist sand and let them stay thus until the next autumn, when berries and sand may be sown together in the open.

**Hydrangea.**—The common hydrangea of the shops is *H. Hortensia* (blue- or pink-flowered). This needs well-drained, richly manured, sandy soil, and adequate supplies of moisture. It is not quite hardy, and outdoors must have a sheltered position. Prune in summer, cutting out all weak wood; thin out stems and remove dead flower-heads. Then cut back the remaining strong stems to within six or seven buds of the old wood. *H. paniculata* is a hardy species with white flowers. This should be pruned in March, stems thinned and others cut back to leave only a couple of good buds at the base of the new wood. *H. petiolaris* (or *scandens*), a climber with creamy flowers, can be left to ramble at will over old tree stumps. Plant all species outdoors in March. Pot up *Hortensia* for indoor culture in February or March.

**Impatiens (Balsam, or Touch-me-not).**—The hardy annual, *I. balsamina*, is useful to sow in spring in partial shade for summer flowering. Pink. 18 in.

**Iris.**—Hardy perennials divided into two main groups, one with rhizomatous roots, and the other bulbous rooted. Plant bulbs in September, 3-4 in. deep, if preferred grow them in pots. Plant other types, including the May- and June-flowering *Irises*, dwarf bearded *Irises* (on rock-gardens), etc., in November. *Iris stylosa*, which flowers from November to March, should be planted in gravelly soil in early autumn. For colours, heights, etc., consult catalogues. All

*Irises* can be raised from seed, but some take several seasons to arrive at flowering stage.

**Ixia.**—South African bulbs, suitable for warm, dry borders or rockeries in full sun. Rich, sandy loam should be provided, and the bulbs set 4 in. deep and 3 in. apart in September. These bulbs can also be grown in pots—six bulbs in a 6-in. pot.

**Jasminum.**—Climbers very useful for porches and house walls. Increased by cuttings or layers in summer. *J. nudiflorum* is the winter-flowering jasmine that carries masses of yellow flowers on bare stems. Cut this hard back after flowering. In a mixed shrubbery it does well tied to pillars in front of tall evergreens, or it can be cut almost to ground level after flowering and allowed to form a bushy mass of stems. *J. officinale* is the white, summer-flowering jasmine. Thin out the stems of this, to prevent crowding. *J. revolutum* is the May-flowering, golden jasmine, best grown as a bush.

**Kalmia.**—American shrubs, evergreen and bearing dainty pink flowers. Best in warm, sandy, leafy soil. Increase by seeds in spring, cuttings or layering in October.

**Kerria.**—Hardy deciduous shrubs with orange flowers, single or double, in March. Useful for almost any soil. Cut out the old wood in June or July, after the flowers have faded. Increase most easily by division of roots in autumn.

**Kniphofia (Red-hot Poker).**—Hardy perennials that prefer well-drained, deep sandy and leafy soil in partial shade. Increase by seed, in March, under glass, or by root division at the same time. Protect plants from frost in winter. Various colours are to be found among "red-hot pokers," mostly flowering in late summer.

**Larkspur.**—See *Delphinium*.

**Lathyrus.**—See *Sweet Pea*.

**Lavandula (Lavender).**—Light, well-drained soil suits these well-known shrubs. Plant in March or September. Clip over each season after the flowers fade, but do not cut hard back into old wood. Increase by cuttings in October.

**Lavatera.**—One of the most showy of garden annuals. Sow in autumn or spring. Avoid transplanting if possible but thin out to allow 1 ft. between the plants. 2-5 ft. Mostly pink, rose, or white.

**Leucojum (Snowflake).**—Hardy bulbs with flowers of white and green, in spring or autumn, according to species, 10-15 in. Plant in September, 4 in. deep in light soil and 5 or 6 in. apart. Lift only when necessary.

**Lilac.**—See *Syringa*.

**Lilium.**—Mostly hardy bulbs, which thrive in a position where the young growth is shaded, but the flowers lift their heads to the sun. Some lilies succeed in limed soil, e.g., *Madonna* and *regal lilies*; others must have sandy peat. Catalogues give information on this point. Lilies can be grown in pots—*L. auratum* is one of the best for this method and can be potted up in autumn. Increase regal lilies by seed (to flower in second year) or offsets, other lilies by offsets, bulblets, or seed.

**Lily of the Valley.**—See *Convallaria*.

**Linum (Flax).**—Hardy annuals and perennials for mixed borders. Sow annuals in spring; thin out to 4 in. apart. Sow perennials in April, or raise from cuttings in July. Colours various, 8 in. to 2 ft.

**Lobelia.**—Useful half-hardy plant for summer bedding. Blue lobelia is raised annually from seed under glass in February. There are also taller perennials with red or purple flowers which are useful for borders: these must be lifted and stored away from frosts in winter, or covered with ash in a warm garden.

**Love-in-a-Mist (Nigella).**—Annuals with blue, purple, or white flowers and delicate foliage: useful as a foil to other flowers in vases. Sow in autumn or in March or April in the open garden. 1-2 ft.

**Lunaria biennis (Honesty).**—Hardy biennial with decorative seed pods after the purple or white flowers fade. Sow broadcast in the wilder parts of the garden, and allow to seed itself.

**Lupinus (Lupins).**—Hardy perennials which can easily be raised from seed. Numerous named varieties are obtainable from nurserymen and seedsmen. There are also annuals which can be sown in spring for summer blooming. The well-known "Russell" lupins are a particularly fine strain of the perennials, with a very wide colour range. 1-5 ft.

**Magnolia.**—Hardy and half-hardy shrubs, deciduous or evergreen. The easiest to grow is possibly *M. stellata*. Plant in April or October.

**Malcolmia.**—See *Virginian Stock*.

**Michaelmas Daisy.**—See *Aster*.

**Mignonette** (*Reseda odorata*).—Scented perennial plants that are normally grown as annuals. Sow in spring, and thin out to 6 in. apart.

**Mimulus** (*Monkey Flowers*).—Hardy and half-hardy annuals and hardy perennials. *M. tigrinus* is a showy annual raised from seed sown under glass, June. 9 in. *M. moschatus* is the species which was once scented, but has now lost its fragrance.

**Monkshood.**—See *Aconitum*.

**Montbretia.**—Hardy bulbous plants, best in rich, sandy loam. Several named varieties, with flowers varying from rose to golden orange, are now obtainable. 2-4 ft. Plant in April, 4 in. deep and 4-6 in. apart.

**Muscari** (*Grape Hyacinths*).—Hardy bulbs useful for rock-garden and border edgings, or for pot culture. Plant in October. Increase by offsets at this time. Blue or white, 8 in.

**Myosotis** (*Forget-me-not*).—Annuals and perennials, but most are grown as biennials; the ordinary *Forget-me-not* used in spring bedding is sown in April or May for the following season, and planted out in autumn when bulbs are planted. Some species are suitable for waterside gardens.

**Narcissus.**—Hardy bulbs of which there are a great many different species and hybrids. The various groups into which horticulturists have divided them include trumpet daffodils, short- and medium-cupped types, bunch-flowered types, and so on. All may be used for spring bedding, or grown under glass or in the home. Plant in August for show blooms, in October for main plantings. Plant rather deeply (daffodils about 6 in. deep) with a little sand under each bulb if the soil is very sticky clay. Lift only when crowding occurs.

**Nasturtium.**—See *Tropaeolum*.

**Nemesia.**—Half-hardy annuals for spring sowing under glass. Seed may also be sown in frames in August and wintered in the frames. Colours very varied. 1 ft. June to September.

**Nemophila** (*Californian Bluebell*).—*N. insignis* is the small blue-flowered annual suitable for border edgings. Sow in spring where it will mature. 3 in.

**Nepeta** (*Catmint*).—Dwarf, compact, gray-leaved perennial with many spikes of lavender-purple flowers. *Nepeta Mussini* is the variety mostly grown. 1 ft. July. Increase from cuttings in September, or divide in spring or autumn.

**Nicotiana** (*Tobacco*).—*N. glauca* is the white-flowered fragrant plant grown for summer bedding from seed sown in February under glass. *N. Sandera* has more colourful, red flowers but lack fragrance.

**Nigella.**—See *Love-in-a-Mist*.

**Oenothera** (*Evening Primrose*).—Annuals, biennials, and perennials. The border Evening Primrose (*O. fruticosa Fraseri*) grows to 2 ft. and carries bright yellow flowers in the evenings, from June to August. Increase by seed sown in spring in a cold frame, or by division in spring or autumn.

**Orchids.**—Tropical plants which need not only a glasshouse, but special soil and moisture conditions. Their culture is therefore only for experts, except for a few of the more easily grown varieties. *Odontoglossum* and *cypripedium* varieties are sometimes satisfactory in the cool greenhouse. There are also some hardy orchids, natives of Britain, which are grown on rock-gardens.

**Pæonia** (*Peony*).—Herbaceous and shrubby plants. The old red peony of cottage gardens has mostly given place to a race of hybrids of great variety of form and colour. Leafy, well-mannered, moist soil is needed, as peonies are gross feeders. A mulch of manure each February over established plants will help. In September increase by removal from the old plants of crowns with roots attached.

**Pansy.**—See *Viola*.

**Papaver** (*Poppy*).—Hardy annuals, biennials, and perennials. Annuals may be sown in spring or autumn. These include *P. Rheas*, the Shirley poppy. Biennials include the Iceland poppy, *P. medicinale*, which is slightly tender and only suitable for warm soil, as it dies off in cold soil if

the winter is severe. *P. orientale* is a useful perennial for any garden, and produces the huge blooms that are a feature of early summer gardens. Plant this in spring or autumn, but do not lift unless the plants are very overcrowded. Increase preferably by root cuttings, i.e., pieces of root of finger-length and thickness, planted with 2 in. of soil over the top of each.

**Passion Flower** (*Passiflora*).—Climbing shrubs, suitable for warm situations or for the greenhouse. Cut back new wood half length in February. Plant in spring or autumn. Increase from cuttings in summer.

**Pelargonium.**—Bedding geraniums and show pelargoniums both belong to this genus. Sunshine in plenty is the main need. Bedding geraniums should be wintered under glass. The best method is to make a practice of taking cuttings each August or September, inserting these round the edges of large pots of sandy soil, in the greenhouse. These can be potted up separately in spring, and used for summer bedding. In early spring it may also be convenient to take some cuttings from old plants wintered under glass. These, if not allowed to flower during summer, will make good pot plants for winter flowering in a sunny window.

**Pentstemon.**—Slightly tender perennials, useful for summer bedding, in a variety of colours, 20-30 in. They can be raised from seed sown under glass in March, or from cuttings taken in August and wintered in a frame.

**Petunia.**—Half-hardy perennials, grown as annuals for summer bedding. Excellent for window-boxes. Sow under glass in early spring. Various colours, June to October. 1 ft.

**Philadelphus** (*Syringa*, *Mock Orange*).—Hardy, deciduous, flowering shrubs which grow up to 12 ft. in height. The flowers are white and often scented—*Virginale*. *P. microphyllus* flowers in June and is a dwarf species, 3-4 ft. high.

**Phlox.**—Hardy annuals and perennials. *P. Drummondii* is the annual of many brilliant colours that is usually sown under glass for summer bedding. 6-12 in. June to October. *P. decussata* is the tall border phlox of which many varieties are sold. 2-4 ft. Plant this with 1½ in. of soil over the crowns in autumn or spring. Increase by division in February, March, or October; by cuttings of young growths in autumn (under glass); or by seed sown in the open in April. This succeeds in partial shade.

**Physalis** (*Winter Cherry* or *Cape Gooseberry*).—Light, rich soil and a sunny position should be provided in order to obtain the best results. The plants are grown for their "lantern" fruits, and stems should be cut when the lanterns are coloured, and hung in small bunches upside down until the stems have become dry and rigid.

**Pinks.**—See *Dianthus*.

**Polemonium** (*Jacob's Ladder*).—Hardy perennials, with blue or white flowers in June. Plant in spring or autumn, 6 in. apart in groups. Divide roots at the same seasons. 2 ft.

**Polyanthus.**—See *Primula*.

**Polygonatum** (*Solomon's Seal*).—One of the best flowering plants for shady positions. Rich, moist soil is best. Plant in autumn or spring.

**Polygonum** (*Knotwort*).—*P. Balduianum* is a rapid-growing climber which is useful to hide outhouses, or to smother old tree stumps. It flowers profusely in early and in late summer, but should generally be kept well away from the house on account of its untidy habit—the flowers and leaves fall in large numbers. Plant in autumn or spring.

**Primula** (*The Primrose Family*).—Primroses and *P. Polyantha*, and the various greenhouse primulas, such as *P. sinensis*, all belong to this large family. So also do certain primulas that love the waterside or bog garden. *Polyantha primrosea* (*polyanthus*) are probably the most useful in the ordinary garden. These can be raised from seed, sown outdoors in April, or under glass if preferred; or old plants can be divided after the flowers fade.

**Pyrethrum.**—Hardy perennials, but only suitable for well-drained, light, rich soil. Lift and divide every other year at planting time in spring. Many named varieties are available in different colours and all grow from 2 to 3 ft.

**Ranunculus.**—Herbaceous perennials useful in groups in a border where the soil is moist and rich. Plant 9 in. apart in groups, in autumn and mulch

with decayed manure each year at this season. Increase by division.

**Reseda.**—See *Mignonette*.

**Rhododendron.**—Evergreen shrubs with huge trusses of flower. Azaleas are deciduous shrubs of the same family. Both need soil that is free of lime, and preferably light and rich; the azaleas should have full sun. Plant in September or April.

**Ribes sanguineum** (the Red Flowering Currant).—One of the best of deciduous flowering shrubs for a town garden. Plant in spring or autumn. Increase by cuttings in autumn.

**Richardia** (Arum Lily).—Plant the bulbs in large pots in October. Light loam with some farm manure and sand is a good compost. Water freely until June—the pot can stand in a saucer of water. Plant out for the rest of the summer, or stand the pot in the open in the shade. Increase by offsets. Yellow-flowered arums are only suitable for greenhouse culture.

**Roses.**—The rose family includes many different species, and innumerable hybrids. All are best planted in November, but planting may continue until the buds begin to break in spring. The main groups are bush and standard roses, ramblers, climbing roses, and hedge roses. Bushes are pruned in late March, the weak wood being cut away first, and then the stronger shoots cut back to induce strong new growths that will carry the season's flowers. Hard pruning is the rule for roses that are weak growers; less drastic pruning for strong growers, otherwise they will make too much new wood and not enough flowers. Standard roses are pruned as bush roses, except that all growths from the base are cut away and only the head allowed to develop. Climbers are climbing types of the same kinds of roses as the bushes and standards, and these are also pruned in March, but care is taken to allow a skeleton of old wood to remain to cover supports. Ramblers are the kind of roses that send up long stems from the base each season. The flowers appear on the wood that is a year old, and after the flowers fade, these old stems are cut right away, and only the young unflowered wood tied into the supports. These are also grown as standards. For fuller details specialist books should be consulted, as there are a great many slight differences in pruning according to the variety of rose grown. Cultivation should include an annual mulch of manure if possible, and the use of bone meal and lime. The usual planting distances for rose bushes in a rose garden are 2 ft. apart for bushes in beds not more than 5 ft. wide.

**Salpiglossis.**—Half-hardy annual with petunia-like flowers, richly pencilled. It flowers in August, on stems 18 in. high, and makes a brave show in a border. Sow under glass in February.

**Salvia.**—Annuals, biennials, and perennials. Annuals are sown under glass in February. Hardy perennials planted in autumn or spring. Half-hardy perennials used for summer bedding are raised from cuttings taken in spring from old plants that have wintered under glass. *S. patens* (deep blue) and *S. splendens* (scarlet) are favourites for summer flower-beds.

**Saxifraga.**—A large family of plants mostly suitable for the rock garden, and of various colours. The Mossy Saxifrages include Peter Pan (crimson) and Elf (pink). Encrusted varieties are smaller like *S. Jenkinsae* (pink) and *S. apiculata* (yellow). Some varieties are only suitable for the Alpine house. *S. Megasea* has large fleshy leaves, and pink flowers in spring; this grows well by the waterside, and in the shade.

**Scabiosa.**—Annuals, biennials, and perennials. Sweet scabious is best raised from seed sown each August to flower in the following summer. *S. caucasica* is a fine blue perennial suitable for cut flowers, best in deep, moist, rich loam in full sun. Increase from seed or by division. Flowers mostly in shades of blue and purple, up to 3 ft. A yellow species, *S. lutea*, grows to 5 ft. and is useful at the back of a mixed border.

**Schizanthus.**—Half-hardy annuals that like rich loam with some mortar rubble. Sow the seed under glass in August, or in the open in April. Colours various, up to 4 ft. according to variety. Good as a pot plant for the cold greenhouse.

**Scilla.**—Hardy bulbs, including the native bluebell. There are also garden types, with blue, white, and rose flowers. Plant in October 2½ in. deep and 4 in. apart. Scillas also make good pot

plants. *Scilla sibirica* and its new variety "Spring Beauty" are good grown in shallow bowls of fibre.

**Sedum.**—A family of plants with fleshy leaves, varying in size from the creeping stonecrops to *S. spectabile*, which carries heads of rose flowers 1 ft. high from July to September. Plant in autumn or spring.

**Sidalcea.**—Hardy perennials with pink, bluish or white flowers, July. 3 ft. Plant in spring or autumn, and increase by division.

**Snowdrop.**—See *Galanthus*.

**Solanum capsicastrum** (Winter Cherry).—Pot plants that carry in winter bright orange fruits like cherries. When the berries shrivel, the plants should be cut back hard and restarted into fresh growth—in February or March. Until that time water should be given, and the plants kept away from draughts, and away from gas fires.

**Solidago** (Golden Rod).—Hardy perennials very easy to cultivate in any soil. Increase by division in spring or autumn. 4–5 ft.

**Spiraea.**—Hardy shrubs and perennials that like moisture and thrive in marshes. *S. japonica* is the moisture-loving perennial that is grown as a pot plant for the market.

**Stocks.**—Mostly half-hardy biennials, but the annual Ten-week Stock is best known of all. All are easily raised from seed in a frame or cold greenhouse, and named varieties of many colours and heights are listed in catalogues.

**Sunflower.**—See *Helianthus*.

**Sweet Pea.**—Hardy annual which has been much improved of late years by hybridisation. Sow in autumn or spring, under glass or in the open. Remove side growths and keep one or two main stems on each plant to produce the best flowers. Support on bamboo canes or pea sticks, and pick flowers as they open. Sweet peas pay for deep cultivation of the soil and constant attention during the summer.

**Sweet William.**—See *Dianthus*.

**Syringa** (Lilac).—(The name syringa is sometimes wrongly applied to philadelphus or mock orange.) Hardy shrubs of various colours. Plant in October or March. Prune as little as possible, and when pruning, cut stems right to the base, or to the point where two stems join: shortening stems after flowering will prevent flowers appearing in the next season.

**Thrift.**—See *Armeria*.

**Tobacco Plant.**—See *Nicotiana*.

**Tropeaeolum.**—The common nasturtium and also canary creeper which has fringed leaves and golden flowers, both belong to this family. Seeds are sown under glass in February or March, or in the open when danger of frost damage is past. A sunny position, and not too rich a soil is best.

**Tulips.**—Hardy bulbs, obtainable in great variety from bulb growers. Plant in November—over-early planting may cause the plants to go blind. Plant 4–6 in. deep with sand under each bulb. Lift tulips (except tulip species and a few cottage tulips) every season when the foliage has died down. Clean, sort over and keep large bulbs to replant in borders. Plant smaller ones in a nursery plot to grow on to larger size.

**Verbena.**—Hardy bedding plants which can be raised from cuttings rooted in autumn and left undisturbed in the pots until February. More cuttings can be taken in February from old plants that have wintered under glass. Stop back the growing points of young plants, to make them bushy. Seeds can be raised under glass in the early spring, in a temperature of 60° F.

**Veronica.**—Hardy evergreens, annuals, and herbaceous perennials, all easily grown and propagated according to the type.

**Viola.**—Hardy plants that include the pansies, tufted pansies, and rock violas or violettas. All can be raised from seed sown in pans of light soil in June, or seed may be sown in the open in July. To obtain a stock of good plants of uniform colour, increase by cuttings at any convenient time between April and October. Named varieties are numerous, and catalogues should be consulted.

**Violet.**—This also is a form of viola. Ordinary violets are hardy and can be grown outdoors all the year round. After flowers fade, the plants can be taken up, the best new outside crowns replanted, and unwanted runners and dying foliage removed. This treatment will ensure better flowers in the following season. Violets can

of course be grown under glass for the market, and many named varieties are on sale for this purpose.

**Virginian Stock.**—Well-known hardy annual that can be sown at any time during spring or summer, to make border edgings. Sow thinly, where it is to grow, and do not transplant or thin out.

**Wallflower.**—See *Cheiranthus*.

**Winter Cherry.**—See *Physalis* and *Solanum*.

**Wistaria.**—Hardy ornamental climber for house walls. Plant in spring or autumn. Increase by

layering in summer. Mauve or white, May and June. Prune January or February as a vine.

**Zinnia.**—Half-hardy annuals for light, rich soil. Sow under glass in early spring. Be careful to avoid damping off. Pot up seedlings singly in small pots, for greenhouse cultivation, or plant out from boxes in June. Red, orange, etc., according to variety. July to September. 20-30 in.

Concrete is suitable for making water-gardens, for the creation of rock-gardens, for stepping-stones, and all kinds of informal footpaths.

Concrete slabs may be built into pergolas and pillars. They can also be fashioned into seats, steps, bird-baths, sundials, and other garden ornaments.

Useful data concerning the mixtures needed are:—

**Paths.**—1 bag of Portland cement, 2½ cu. ft. of sand, and 3½ cu. ft. of shingle will make a path 2 ft. by 15 ft. Is laid 2 in. thick.

**Small flat stones.**—6½ bags cement to 1 yard sand. These can be used for paving, to build into pillars, and to make retaining walls.

It is best, if making pillars and pergolas and walls, to prepare quantities of slabs first, and build them later into the structures required. The effect is better than if large unbroken surfaces of concrete are left on view in the garden. Such surfaces are only artistic if they are absolutely perfect in detail, and where very large pools, bridges, and similar features are to be made of concrete, the construction is best put in the hands of contractors.

**Water in the Garden.**—Rock- and water-gardening of an informal type, where water falls from pool to pool down a rocky slope, or trickles over a bed of shingle on its way to a bottom pool, and water-gardening of more formal character, where a water-lily is surrounded by flat stones laid flush with the lawn—both these extremes, and many variations of them, can be undertaken by an owner-gardener. Small pumps, run by electricity, can be obtained to circulate the water in the hill-side water-garden. In a flat, open pool where water-plants are grown, no circulation of water is required, as the oxygenating plants in the water will keep it fresh and clean.

To construct a formal pool, first excavate the soil to a depth and area sufficient to allow for a 6-in. wall all round. Roughly nail together old boards to make a framework that will fit inside and come above the rim, and will allow for the wall thickness. Begin by mixing concrete as advised above for paths, i.e., with sand, shingle, and Portland cement. Put a 6-in. thick layer all over the bottom of the hole. Then set the wooden framework in position, and fill in a similar mixture between the wood and the surrounding soil. Do this as soon as possible after laying the base, so that wall and bottom of the pond are bound well together.

It is essential that the framework should be easily removable, and this will be so if few nails are used in assembling and the wood is rubbed over with some kind of oil before the concrete is laid.

Above the rough wall, any kind of finish can be made, when the concrete has hardened and the framework has been removed. For instance, rough slabs may be built to lessen the formality of the pool, or flat pre-cast concrete slabs may be laid flush with a lawn, or built into a low wall, as desired.

A depth of 2 ft. of water will allow the cultivation of many lovely water-lilies, but a depth of 10 in. is enough for the cultivation of pigmy types, and of many other water-loving plants.

## II. FRUIT

Preparation for fruit culture includes three things. First, the selection of the best available site. Fruits are often ruined by spring frosts, particularly in low-lying districts. The effect of a late frost is worse when the rising sun shines directly on to the trees, so that a slope facing east is undesirable. However, the choice of sites is for most of us very limited. The second important point is to choose fruits and varieties that are most likely to succeed, and to be of use to us, taking into consideration the aspect of the site. Family needs and personal tastes will, of course, enter into the question here. Finally, the soil must be suitably prepared for the fruits that are to be grown.

Some fruits will grow on walls. Some can be trained to wires strained between two posts, so that they can, if desired, edge a walk through the kitchen garden. Some fruits grow reasonably in partial shade: others need full sunshine. Before any detailed order is sent to a nursery, all these things should be considered, and the following information concerning popular garden fruits will be a useful guide to the novice in garden matters.

**Apple.**—A good, deep loam is best for apples, preferably with a sub-soil of clay or chalk. For gardens it is best to buy trees on dwarfing stock (Malling IX), as these come into bearing quickly and never grow to very large trees. Plant in October, or before March, stake immediately, and from time to time renew the ties, to make sure that the tree is secure, but that the tying material allows for sufficient stem growth. In districts where rabbits may be troublesome, protect the base of the tree by a surround of wire netting; otherwise the rabbits will gnaw the bark, and if the bark is removed all round the tree, it will die. Remember fertility rules: at least two apples should be grown unless there are many other apples in the neighbourhood. These two should flower at the same season and cross-pollinate each other. Laxton's Superb and Ellison's Orange would make a good dessert pair. Laxton's Superb and Lord Derby if a cooker is wanted. When planting apples allow 12 ft. from bush to bush—more space still if large standards are to be grown. Manure with garden compost or farm manure if the ground is dry and poor. Use potash in winter on all dessert apples, and a complete fertiliser in spring when the fruit is setting. (For information re spraying and feeding of apples and all other fruits, see Section VI.) Prune in winter, cutting back side growths on

most varieties, to encourage spur formation. Shorten leaders to encourage bushy growth and make the bush symmetrical. Certain apples bear fruits at or near the tips of young shoots: these varieties must be pruned differently. Some of the shoots can be taken out each season, and others left full length to carry the fruit. It is important with this type of pruning that stems should not become too crowded, though a somewhat straggly appearance as compared with other apples must be expected. These varieties are described in catalogues as "tip-bearers."

**Apricot.**—Plant in October in well-drained, calcareous loam, dug to a depth of 3 ft. and well dressed with bone-meal. A position against a sunny wall is good. Allow 10 ft. for the spread of the tree. Fruits grow on young wood a year old. Pruning should be finger-and-thumb pruning in summer to encourage sufficient young stems; remove the tips of stems that are fruiting, and to get fine specimens thin out fruits when the size of peas. Hemskirk and Moor Park are useful varieties for gardens.

**Blackberry.**—Heavy dressings of farm manure or garden compost, or a bucket of poultry droppings washed in with plenty of water in July or August, will produce fine fruits and strong growth. Use blackberries over old banks, or to cover tool-houses and other odd buildings. Himalayan

Giant, Merton Thornless, and Parsley-leaved are three useful blackberries. Plant in October, and increase by layering in summer.

**Cherry.**—Where one cherry only can be grown plant a Morello cherry, which will thrive almost anywhere, even on a north wall in a town garden. Other cherries should be planted in pairs for cross-pollination, and these pairs should be selected very carefully, since cherries do not necessarily cross pollinate each other because they are in bloom at the same time. The advice of an expert should be sought on this matter if much planting is done. Where two sweet cherries only can be planted, a good choice would be Emperor Francis (white heart) and Governor Wood (red and yellow.) When needed, prune in autumn, but as little as possible after the tree has been formed.

nate years, and if half the bushes are so treated each season, the result is good. Pruning of red and white currants is more on the general lines for apples and other spur-fruited subjects. After fruit is gathered broken stems are cut cleanly away, and at the same time the side growths are pinched back a little to prevent too much overcrowding. In winter these side growths are shortened to within a few inches of the old wood, or to allow a couple of good leaf buds as well as the fruit buds on the "spur." At the same time symmetry is encouraged, and the heart of each bush is kept open so that air and sun can reach all stems, and so that fruit gathering is made easier.

**Damsons.**—A variety of plum which is very hardy and often used as windbreak alongside large orchards. It succeeds well in chalky loam

CROSSBAR

SINGLE

TRIPOD

**THREE METHODS OF STAKING FRUIT TREES, cross-bar, single, and tripod.** In each case protective material is used to prevent the tie cutting the tree. Ties must be examined and renewed once a year.

**Currants.**—Two distinct types of currants are grown—black currants and red currants. White and pink currants are varieties of the red, with similar habit of growth. Black currants need rich, moist loam and plenty of sun, though they succeed fairly well in partial shade. Red and white currants like similar soil, but will also do well in light soil. They can be trained against house walls if desired, and they are more tolerant of dryness in the soil. In planting any of the currants as bushes in the open garden, allow at least 4 ft. each way, 5 ft. apart is even better. Plant in October, or during the dormant season, when there is no frost in the soil. Increase all types by cuttings taken only from perfectly healthy plants. These cuttings can be pieces 10-15 in. long, stripped of lower leaves (if still present) and inserted in the open, in rows, about 6 in. apart, in November. At least half the cutting should be buried in the soil. In the case of red and white currants, the lower dormant buds should be picked out at the time the cutting is inserted. This will prevent the appearance of suckers and allow for a short "leg" above the ground before the head develops. In the case of black currants the dormant buds should all remain, as growths from the ground level are to be encouraged, since the black currant fruits best on young wood. Pruning of black currants can be done as soon as possible after the fruit is gathered, and it should consist of the removal of as much old wood as possible, and encouragement of young growths. Where strong basal growths are appearing, these should be retained and the old wood all cut right out. If only young wood from the old stems exists, use discretion and keep some of the best stems, while cutting others hard back. With some varieties it seems best to cut down the whole plant very near the ground level in alter-

over clay sub-soils, but not in sandy soil unless this is very well treated during preparation. Plant from October onwards, 15 ft. apart for ordinary standards. For hedging and wind-breaks they can be planted closer. Prune in early years to form a shapely tree; later cut out dead wood only, and keep the growths from getting overcrowded. Old damsons can be pruned as hard back as desired without permanent harm.

**Figs.**—Plenty of sun and air are needed for figs, and in order to encourage ripening of the wood (essential to fruit production) a restricted root run should be provided. The hole prepared for the tree, about 4 ft. square, can be bricked in, but usually a position alongside house foundations is sufficiently restricted. A chalky sub-soil is very suitable for this fruit. Pruning in winter should consist of removal of the old fruiting shoots, and tying in of new growths. In early summer the number of new shoots allowed from each of these newly tied-in growths should be strictly limited—one at the tip to extend the branch, and one at the base of each shoot to become a fruiting stem in the following year is the usual number of buds to leave. At the end of summer these are stopped above the sixth leaf. In autumn any fruits that are larger than pea-size should be removed, as these are almost certain to be frost damaged, and the vigour of the plant is best allowed to go into the small fruits which will swell in spring. "Brown Turkey" is one of the best figs to grow outdoors.

**Gooseberries.**—Almost any soil and situation will do reasonably well for gooseberries, but a deep, rich loam, in full sunshine will produce the best fruits. Plant from October onwards and increase by cuttings taken as described above for red currants. If possible, grow each bush on a "leg" of about a foot before any side branching

is allowed. Bushes may need as much room as 5 ft., or even more.

**Grapes.**—Outdoor grape vines should, if possible, be against a south or south-west wall. If cultivation is good, ripe grapes will then be obtained. In any case, an outdoor grape vine is attractive on account of its foliage. Chalk and mortar rubble at the bottom of the hole prepared for planting, calcined bones mixed with the next layer of loam, and fibrous loam mixed with garden compost to complete the site will be found good. Plant in spring, setting the stem 1 or 2 ft. away from the wall, the roots well spread out in a half circle about a foot below the surface. One or more main stems may be allowed to develop, and these will be shortened a little each winter. The side growths will be carefully spaced by removal of unwanted growths, and sub-laterals on these side growths will carry the flower and fruit trusses. To encourage flower formation on these sub-laterals the tips of the new growths will be nipped off—in the first place they will be shortened to about a foot long in summer, and in winter they will again be shortened to leave only one or two dormant buds at the base. This summer and

**BUSH FRUITS** are easily increased from cuttings.

With red and white currants and gooseberries the lower buds are removed as shown on right. Lower buds on blackcurrants are left on. Soil level is at A.

winter pruning of the new wood is continued each season—the summer pruning to leave either a stem about a foot long, or a stem carrying a fruit truss a couple of leaves beyond the truss, and the winter pruning to leave only a few dormant buds near the old wood so that sufficient new growths will develop in spring.

**Loganberry.**—Hybrid berries of similar growth to blackberries, and needing the same kind of cultivation. The loganberry, in particular, responds to generous treatment in the matter of liquid fertilisers and mulchings. Ruthlessly cut out all old stems each autumn, as raspberries are treated. Increase by layering in summer.

**Medlar.**—A broad-topped tree of attractive appearance occasionally found wild in southern counties of England, but probably not indigenous. Plant between October and March, in any reasonably good soil. No pruning when the tree is once formed. Fruit is gathered at the end of October or mid-November, and laid out on trays, eye downwards, until it has bletted, i.e., become partly rotten and soft enough to be palatable. Jelly can be made from the fruits before they are fully ripe.

**Melon.**—Some melons can be grown in frames, and some in glasshouses, in both cases the culture is similar to that required by cucumbers. Under glass seed should be sown in January, one in each small pot of sandy soil, the seed being pressed down  $\frac{1}{2}$  in. into the compost. Temperature 65° F. For frame culture sow seeds a little later, in the same way. Plant in the soil of the frame, or in the greenhouse bed as for cucumbers. Allow five or six pairs of side shoots to show up on the main stem, and then stop the stem at the top. Stop the side shoots after a female bloom has formed, allowing one leaf beyond this bloom. Fertilise the flower artificially by pressing a male flower with dusty pollen centre, over a female flower, and giving it a slight twist. Syringe night and morning, and give plenty of water and liquid manure

at the roots when the fruits are swelling. Should many fruits form on one plant it is wise to restrict the number to three, as they will be of better quality.

**Nectarine.**—A similar fruit to the peach, except that it has a smooth instead of a velvety skin. It is cultivated in exactly the same way as the peach, but the flavour is rather fresher, and preferred by some. For further details see Peach.

**Nuts.**—The most common nuts grown in this country are cob-nuts and their variety filberts, walnuts, chestnuts, and occasionally almonds. The nuts of the forest beech (beech mast), and certain pine kernels are edible, but are not actually grown here for their food value, though they are sometimes collected and eaten.

**Almonds** are usually only grown for the sake of their early pink flowers, which appear on leafless stems in March. The nuts of these flowering almonds vary considerably. Taste may be con-

**GRAPE VINES** are pruned during dormancy.

The young growths are cut back to two eyes as shown. During growth the young shoots are stopped to three leaves beyond the bunch of grapes. Laterals are also pinched out after the first leaf.

sidered as a good guide to their edibility: the most bitter should be avoided, those rather bitter to eat may be mixed with sweet almonds or other nuts in the making of marzipan and cakes, while sweet-tasting almonds are always safe to eat. If trees are planted for their fruits a nurseryman should be consulted before purchasing. Plant October to February in ordinary loam.

**Cob-nuts and Filberts** are closely allied to the wild hazel nut, and also to the Barcelona nut which is sold shelled, or unshelled, in large quantities for Christmas fare. The difference between hazel nuts and cobs or filberts is mainly one of size, due to cultivation. The difference between the cobs and the filberts is that the cob-nuts have husks only part way up the nut, whereas the husk of the filberts completely envelopes the nuts. There are naturally many different varieties of both nuts—varying chiefly in size, in colour, in the hardness or thinness of the shell, and so on. These nuts should be planted in October, in a position sheltered from north and east winds. Poor gravelly or stony soil is quite good, and rough corners of a garden can often be used for nuts. Each tree will need 15 ft. each way. Pruning is generally done in March, after the pollen has fallen from the catkins. Strong side growths are cut back to a catkin near the

base of each. Wood that bore fruit last season is cut back to leave only two or three buds at the base, and suckers are cut right away. The young twiggy growth of the last season is left as much as possible as this carries the flowers and the nuts. If very strong side stems grow again by August, these are usually broken ("brutted") about 6 in. from the base, and left hanging until pruning time. This prevents so much unnecessary crowding. If the nuts are to be stored, gather them when they begin to fall from the husks, and lay them out to dry. Then pack into jars with layers of salt between the layers of nuts, and they will be in good condition at Christmas-time.

**Walnuts.** These are tall decorative trees, but it is usually many years before a young tree bears fruit. There are, however, trees specially grafted to produce early fruiting, and nurseries should be asked about this when walnuts are ordered. Plant October to March, and make sure the tree does not suffer from dryness at the roots in the first season. If it comes after new growth starts in the spring, frost is very damaging to walnuts, and for that reason it is useless to grow walnuts where spring frosts are often troublesome late in the season. Gather walnuts either green for pickling (before July 15th was the old-fashioned instruction, but anyway before the shell begins to harden). Otherwise gather them when they begin to fall, take off the outer green husk at once, and if the nuts are to be stored pack them in jars of salt as described for cob-nuts. (Walnuts are improved if the shells are bleached before storing.) If moistened coconut fibre can be used in alternate layers with the salt, the nuts keep in even better condition than with salt alone.

**Peach.**—As previously stated, peaches and nectarines are nearly related, and both are treated in the same way in the garden. These trees can be grown in the open garden as bushes or standards in very warm, sheltered districts, but they are more often grown as wall-trained trees.

Fan-trained is the usual type, and pruning is done more or less all through the growing season, with the object of keeping the tree to its proper shape, and restricting the growth of unwanted stems. Fruits appear on young wood only, and finger-and-thumb pruning of tiny developing buds is practised to avoid the waste of the plant's strength. In winter there should be, a number of strong stems of the current season's development, and these are the stems that will bear the fruits. They should have fruit buds visible, and also many leaf buds, and as soon as these leaf buds begin to grow in spring, and the growths are about an inch long, the tips are nipped off, except in the case of the few that are chosen to become "replacements." All shoots that are growing out at right angles to the wall will be nipped, so also will some of the others, leaving about 5 in. between each pair of unpruned shoots. When the trees are fruiting well, one strong shoot will be allowed to grow from a point near the base of the shoot that carries the fruit: this will, after the fruit is gathered, be tied or nailed in instead of the present fruiting stem which will be cut right away. This brief summary of the pruning method to be adopted is naturally not complete, and every grower should seek the advice of an expert if any doubt arises over this matter.

Bellegarde peach and Pitmaston Orange nectarine are good varieties for a small garden.

**Pear.**—Pears can be grown in most districts where apples succeed, but pears are a little more susceptible to extremes of climate, and therefore do better in the southern half of the country. Pears may be grown in the more difficult districts as wall trees, and a variety such as Conference is especially good grown in this way. Pears, like apples, fruit best if effective cross-pollination can occur, and Louise Bonne would be a useful variety to plant with Conference to ensure fertility. Double Williams and Fertility Improved are tetraploid varieties which will succeed in isolation. Plant pears from October to March. Prune as advised for apples, but it will usually be found that pears form fruiting spurs without much assistance from the pruner, and older pear trees may often be left unpruned. Wall pears will, of course, be kept under constant observation. Superfluous shoots must be rubbed off during summer, to prevent the formation of unwanted

breast wood. Wall pears can take the form of fan-trained trees, espaliers, or triple cordons—espaliers being the most popular method of training.

**Plums.**—Plum-trees are extremely easy to cultivate, and some varieties, such as the well-known Victoria, are very regular croppers, though occasionally plums do get damaged by spring frosts. The trees should be planted in October or as soon after as convenient. Stake at planting time, and be careful to avoid damage to the stems, as open wounds are a source of trouble. Prune as little as possible; if the tree is young when purchased and must be pruned to form the symmetrical shape desired, prune as much as possible with finger and thumb, and avoid large wounds. Silver-leaf disease spores are very active in mid-winter, and for this reason the trees should be pruned preferably in late spring, or if large branches must be removed, do this in summer. Always paint over large wounds immediately, with creosote or white-lead paint to prevent infection, and never allow wind-damaged

WRONG RIGHT WRONG WRONG

**PRUNING**—right and wrong methods of making cuts. Pruning secateurs should be dipped into creosote occasionally while pruning to prevent the spread of Silver Leaf disease.

branches to remain with open, splintering wounds, but cut them cleanly away at once. If crops are very heavy, thin out the fruits while they are very small, and provide supports for pendulous branches as the wood of plum-trees is extremely brittle. Most plums do not need much potash, but the Pershore varieties (Yellow Pershore and Purple Pershore) are rapidly affected by shortage of this fertiliser and can usefully be given potash dressings each winter.

**Raspberry.**—The best time to begin raspberry cultivation is in autumn, when rooted suckers are being lifted from raspberry plantations to make room for the other canes. Unless these come from obviously very healthy plantations, it is not wise to accept them as gifts from friends' gardens, as the raspberry-virus disease is so often present in old plants. It therefore pays to buy from nurseries where the plants are constantly inspected. Raspberry plantations will last about ten years if they do not become affected by disease. Plant the young canes in November, either in groups of three with 4 ft. between the groups, or in lines of canes set 1-2 ft. apart in rows 6 ft. apart. Cut down the newly planted canes in spring to a foot from the ground. This seems drastic, but it is the only way to obtain good, strong stools.—Every autumn the canes that have fruited are cut away, and the strongest of the others left to carry the next season's crop. These are tied in to the supports in the early months of the year, the tops, if affected by frost, being cut back just a little. It is best not to tie the young canes until they are well ripened. To obtain autumn fruits, cut away the old canes in June or earlier, as soon as young canes begin to grow. At the same time give a mulch of good manure or garden compost, and see that the water supply is well maintained if dry weather occurs. The canes will then bear good crops of fruit in the autumn. Keep down the number of canes when growing for autumn fruit, so that the remainder will have every chance to

develop rapidly. Lloyd George, Norfolk Giant, and Yellow Antwerp are useful varieties for summer fruiting, November Abundance for autumn fruiting. Lloyd George is also useful for autumn fruiting, but if it is to be grown in this way the old canes must be cut right down early in the year.

**Strawberry.**—A fair amount of garden space, and soil deeply dug and enriched with manure is needed for successful strawberry culture. Old woodland that has been cleared has been found particularly good for these fruits. The usual way to keep a plantation going in a garden is to remake a third of it each year, setting out freshly rooted runners in place of the old plants. Thus there are always strawberries of one, two, and three years old in the plantation, and a uniform quantity of fruits may be expected. If strawberries are being grown on a kitchen-garden plot, it is best to work down the plot gradually, growing vegetables before and after the three seasons of strawberry cultivation, so that fresh ground is always used for the one-third new plants. In some gardens it pays better to grow annual strawberries, of the alpine-strawberry varieties, or to raise these from seed every other year, sowing the seed in spring or autumn, and setting out the plants a foot apart in rows 18 in. apart. There are also perpetual-fruited strawberries that fruit in the later half of the year. For normal strawberry beds, however, planting is done in August or September, when rooted runners can be obtained. These are set out in the prepared bed 15 in. apart in the rows and with 2-3 ft. between the rows. When planted, the crown of each plant should be just above the surface of the soil, which should be made quite firm round the plant. Watch for frost action in the first winter particularly: if the plants are lifted in the soil after hard frost, press them back again carefully. Top dress the new plants with good compost or decayed manure in early spring, and a few weeks later, when flowers are beginning to show, lay long straw down be-

tween the rows, to prevent the fruits being mud splashed when rains occur. It is a mistake to put straw down too soon if frosts are likely, but should frost threaten after the straw is laid down, protection can be given to the flower-buds by lightly lifting the straw with a fork, so that it forms a loose cover over the plants. It must, afterwards, be laid back between the leaves and the soil. After the fruit is gathered, *i.e.*, in autumn, the straw still remaining on the bed may be drawn a little away from the old plants and burned over, choosing a day when there is a slight breeze and setting light to one end so that the fire travels right across the strawberry bed. The plants will not be harmed by the burning, but fungus spores of certain diseases will be destroyed, and the new growth will be all the healthier for this treatment. Moreover, the slight amount of potash from the straw ash will be of assistance to the plants. During the summer, runners will develop from old plants, *i.e.*, long, thin stems with tufts of green leaves. If these tufts are left to chance, they will root somewhere in the soil, and so form new young plants. It pays the cultivator, however, to prepare special soil for them. The best method is to fill small thumb pots with good compost such as is used for potting (half loam, quarter rotted manure, quarter sand) and to sink these small pots up to the rim near the parent plants. Each runner is then pegged down, with a hairpin or other peg, into a pot of prepared soil. Roots form very rapidly, and in about four weeks the runners can be cut from the old plant, and moved to the new bed that is ready for them. It is very important, when treating runners for the new plantation, to make sure that each comes from a healthy, fruit-bearing old plant, not from one that is diseased or that has failed to produce fruit for any reason.

Vines.—See Grapes.

Walnut.—See Nuts.

(N.B. For details of feeding, and spraying, of all fruits, see Section V on Garden Chemistry.)

### III. VEGETABLES

The vegetable-garden is, today, perhaps the most important part of any home garden. The need for growing a major part, if not all, of the fresh vegetables that a family will consume is twofold. In the first place it pays: homegrown supplies are much cheaper than those in shops, and they come to the kitchen in much fresher condition, so that the true value of green crops and salads, the vitamin value, is not lost. In the second place there is a real national need for greater food production, and the owner of any plot of land, however small, is performing a national service if he grows in it a part, at least, of the family's food.

In selecting the site for the vegetable crops, an open, sunny position, where air is plentiful, is ideal. If strong winds come from a cold quarter, some kind of shelter screen can be provided. This might be a thick holly or thorn hedge—thorn is an excellent wind-break even though it loses its leaves in winter—or a temporary structure of wattle hurdles. These are useful in a new garden to keep off cold winds until a more permanent wind-break can be grown. When a hedge is formed, the wattle hurdles will still be found useful to make temporary screens round individual plants or crops, or to keep draughts away from the cold frame.

Paths through the vegetable-garden are important, as manure will have to be barrowed on to the plot and other heavy loads will have to be wheeled from there to the kitchen door, or to the storing shed. These paths need not be elaborate: a rolled-soil track may be enough, but on sticky clay soil a cinder-covered track will be cleaner than mere rolled soil. Path edgings of a single or double line of brick, set lengthwise, are very useful. They allow for the use of weed-killer on the path, without this penetrating to plant roots in the beds—a point which must be watched carefully, as considerable damage can be done by the careless use of weed-killers near growing crops. A line of annual flowers alongside the path edge makes a walk through the kitchen-garden pleasant, and these can be double-purpose flowers—herbs for culinary use, or flowers to cut for house vases.

In laying out the vegetable plot, ease of working should be kept in mind. The lines on the plot will run as nearly as possible north and south. This allows for a uniform amount of sunshine to reach all the plants, for sunshine to penetrate between the plants to the lower leaves, and it also prevents plants being drawn sideways in the rows in a garden where only the midday sun is effective. These north and south lines should not be too long. If the plot is very long from north to south, a central path should be made. Otherwise there will be rather too much soil trampling in reaching the crops that are some distance from the path, and there will also be more difficulty in harvesting.

Generally speaking, the home garden is not large enough to warrant the cultivation of all the potatoes that will be needed by the family. This is a crop which can probably be grown more economically by farmers. It is, however, worth noting that farmers judge the quality of a potato by the size and appearance of the crop. They are not so much concerned with the flavour, and discard a good-flavoured variety if it does not crop heavily. If, therefore, the gardener can make room for potatoes, the varieties which are of the best flavour can be grown, and these will be found very superior to the usual market varieties. This is a matter for the garden owner to decide for himself, but it affects the lay-out of the vegetable-garden considerably. If potatoes are cultivated, a four-year cropping plan can be adopted. One-half of the ground is probably not too much for the family man to allocate for potatoes: the other half can be divided into two, with main root crops on one quarter of the whole vegetable-garden, and peas, beans, onions, celery, tomatoes, and leeks on the remaining quarter. Green crops will follow the potatoes on the same half, as these will be planted out in succession as the early and then later potatoes are lifted. Some of these greens will, naturally, still be on the plot in the early part of the second year, but these will be followed by tomatoes, leeks, and celery, none of which need the ground in the early months of the season. The two groups of roots and miscellaneous crops will change over in the second

season to the half occupied by potatoes: in the third year they will return to their original half, but their positions can then be changed over so that the quarter occupied by roots in the first year is occupied by the miscellaneous crops in the third. Thus potatoes will be grown on the ground in alternate seasons, and other crops only once in four years on the same site.

Where potatoes are not wanted in such quantity, a rotation of three plots—potatoes (and greens) in one, peas, beans, etc., in one, and roots in another—of equal size may be more practicable. If large quantities of greens are needed, these could take possession of a third of the ground, potatoes (earlies only) and other roots another third, and peas, beans, and other oddments the remainder.

The idea behind all this change-over of crops, which every gardener must work out to suit his particular needs and his particular site, is that each crop will take from the ground a larger proportion of some plant foods than of others. If, therefore, the crop is changed, it becomes easier, and less costly, to maintain the balance of available soil food: less fertilisers are required over a number of years. This, however, is not the only advantage gained by rotation of crops: if it were, the owner of a small garden need never trouble, since the quantity of added fertiliser needed to bring the soil back into condition would be so small that it could be ignored. Perhaps a much more important point is that plants are easily affected by innumerable diseases of more or less virulent character. Many of these are carried in the soil from season to season. The same thing can be said of plant pests—there are some that attack only certain kinds of crop. If the crop is grown year after year on the same site, these diseases and pests lie in wait in the soil and thrive on their plant hosts. If a change-over is made, and the pests and diseases have no suitable host for a season or two, they tend to die out and so leave the crops free from their undesirable attentions. As long a period as can conveniently be arranged should therefore be left between the use of each site for the same crop, for some diseases and pests may linger for several seasons in the soil.

**Soil Preparation.**—Preparation of any soil for vegetable cultivation may be done in this manner. If grass or weeds cover the surface, the tops should be cut off with a sickle or scythe, but there is no need to take off the turf, as is sometimes done. Indeed, this is wasteful, since the fertile part of any soil is the top layer which has been acted upon by weather, and by the bacteria associated with all plant growth. Tall weeds with seed-heads may be burned if desired, but normally any top growth on old plants that is likely to decay should go into the making of garden compost, and the first step on a rough

and another opened at the same time. This continues all down the plot, until the last trench is filled with the loose soil taken from the first one.

This double-digging process should be practised whenever convenient during the winter, and if time allows, the top layer of soil can be turned again and again with the digging fork or spade, so that it becomes well aerated. Frequent turning is ideal for clay soils, that is for the type of soil that sticks to your boots in wet weather and sets like concrete in dry weather. This soil is fertile, and, if it is constantly worked, and manured with leaves, straw, or garden compost, very good indeed for vegetable crops. Sandy soil, which is cleaner to work, is less fertile, and needs plenty of organic manure (decayed living matter) to assist it to hold moisture, but the same treatment, i.e., deep digging and liberal manuring, will make sandy soil more fertile and clay soil easier to work. Both types of soil should be dressed with lime after digging, to prevent sourness, which is a common cause of trouble among vegetables. Chalk is the best form of lime for sandy soils.

It is not always convenient, nor even desirable, to double-dig a plot that is idle only for a week or so in summer. At this season the better treatment may be light forking, or even just hoeing the surface. For instance, where peas and beans have been grown, the soil is always left rich in nitrates (see Section V), and it is sufficient to clear the surface and then plant out winter greens, or to sow onions for the following season, both of which crops will appreciate the nitrates and will not be averse to well-settled sub-soil.

**Manure and Fertilisers.**—Apart from the regular use of lime, some crops need certain extra plant foods. These will be mentioned in the following detailed instructions for cultivation, but the gardener should also keep in mind the general instructions, given in Section V, regarding the use of different fertilisers on different kinds of soil, at different seasons, and so on.

The vexed question of how to obtain manure is partly answered by the compost heap. This is a heap of decaying organic matter, with soil, and usually a little additional plant food, which, when properly composted, makes manure that is not inferior to farm manure. A compost heap can be made on a part of the vegetable plot itself, or it can often occupy an odd corner in the garden, and if it is screened by an evergreen hedge, wall, hurdle, or fence, it need not be at all unsightly.

A site about 4 ft. by 9 ft. is large enough for the allotment-holder's plot, that is for a garden 10 yd. by 30 yd. Make the heap on one half of the marked site. To build the heap is first to put down a layer of waste matter such as plant tops, vegetable trimmings, lawn mowings, soft clippings from hedges (but not woody material), fallen leaves, and all kinds of kitchen waste that will decay. Make this layer about 6 in. thick when well trodden down. Then put about 2 oz. each of superphosphate of lime and sulphate of ammonia, or about 4 oz. of calcium cyanamide, or a dressing of some commercial "compost-maker" (quantity according to makers' instructions) over this material, and if the weather and material are dry, water well. An inch or two of fine soil should then be used as a covering, and with this may be

**DOUBLE DIGGING.**—Land is improved by double digging every three years. The trench at A, 12 in. wide, a spade deep, and soil placed at B. Soil from D fills trench at C, and the first soil B fills trench at E, the finish of the plot. In double digging the sub-soil remains where it is, but is broken up as each new trench is made.

patch will be just to cut down and rake off this rough material, stacking it in a pile for future treatment.

The land should then be double dug (two spits), and for this a trench is first opened along one end of the plot. The material excavated during the process is kept carefully on one side, as it will be needed to fill up the last trench when the whole plot is dug. The trench should be at least 15 in. wide and 1 ft. deep. The loose soil should be lifted out with a spade, and it will then be possible to get into the trench and use a large digging-fork to break the sub-soil. At the same time, if convenient, some manure may be mixed with this lower spit of soil, but where grassland is being broken, the turf from the next 15 in. strip of ground should be lifted off, and thrown in, upside down, in the open trench after forking. The next 15-in. width is then turned over to a depth of 12 in., the soil being thrown in, upside down, in the first trench, thus one trench is filled

thrown any available bonfire ash obtained by burning woody refuse, such as tree prunings. If waste material is obviously diseased, this, too, should go on the bonfire rather than the compost heap, but weeds that have gone to seed do not matter much, as properly composted material should ferment sufficiently to destroy the germinating qualities of these seeds.

Beginning again with a layer of organic refuse over the soil, then more fertiliser or compost maker, then soil, continue gradually to build up the heap until it is about 4 ft. high. The compost will sink quite a lot during the time it is being collected, over a number of weeks, so that more and more can be added. As a rule a heap made in this way is fit to turn at the end of a month or six weeks. At this stage the inside should be hot, and the outside should first be stacked on the remaining half of the site allocated and the hotter material from inside should be packed all round and over it. When this has

RIDGING is a form of digging for wet clay soils: it allows air and frost to break down the clay.

been done, the heap should be covered with soil, well packed, until it is wanted for use in digging. If a heap is built up during spring and summer, covered and left by August, it should be fine to dig into the ground during the winter. In August a fresh heap could be started, and this will be covered after the ground has all been cleared for the winter, and should be useful material to make special beds for such greedy crops as celery, etc., during the spring and early summer.

**Nursery Bed.**—In connexion with every kitchen-garden there should be a nursery plot, i.e., a bed of good, fine soil in which seeds can be sown, and seedlings pricked out, to supply plants for the main vegetable plots. A plot open to the sun, and not overhung by trees is best. Where shade is wanted it can be provided artificially, but without sun many small seedlings merely become drawn and weak and never make good plants later.

Seeds in the nursery bed are generally sown in shallow drills, i.e., in parallel lines drawn with a sharp-pointed stick, about eight inches apart. This allows for the use of the hoe between the lines, while the seedlings are very small, so that weeds can be kept down. A dusting of lime and soot over the seed-bed, raked in a day or two before the seeds are sown, will help to keep away pests: the mixture of soot and lime gives off fumes which discourage the pests. If slugs are known to be troublesome, as on certain clay soils, the use of slug-killer on the seed-plots is a sound practice. In all cases, seeds sown for transplanting should be sown thinly, and thinned or transplanted before any crowding takes place.

## ALPHABETICAL LIST OF GARDEN VEGETABLES

**Artichokes.**—These are of two kinds, Jerusalem artichokes and Globe artichokes. *Jerusalem artichokes* are plants resembling sunflowers in growth. They are often reputed to grow in poor soil, but actually they pay for good cultivation. A double, staggered row of tubers set 4 in. deep and 15 in. apart at the coldest end of the plot acts as a good wind-break, and if they are provided with a strip of richly manured soil, they will

produce a crop of good-sized tubers that are second in food value only to the potato. At the year end, when the tops are cut down by frost, the tubers should be lifted, sorted over, and some of the most shapely ones reserved for planting the next season: this selection of shapely tubers will keep the general quality of the crop good. Planting can be done at any time from the end of January onwards, when there is no frost in the soil. *Globe artichokes* need a good deal of room, and must have deep, rich soil. They are often grown in the flower border for the sake of their ornamental appearance. The part eaten is the unopened flower bud, and unless cultivation has been good, these will be hardly worth cooking.

**Asparagus.**—A plantation of asparagus can be obtained by seed sowing in spring, planting out the seedlings in autumn or the following spring. There are modern strains that come early into bearing, but it takes some time to establish a good plantation. Probably the best way is to buy three-year-old plants. These are set out in rows 18 in. apart, three rows being allowed for a bed of 5 ft. wide. Beds should not be wider, as this is the maximum that allows for easy cultivation. Between beds if many such are planted, there should be rolled soil tracks, for walking, and the top soil may conveniently be taken from this part of the ground and used to build up the beds. Good, rich, preferably rather light loam is ideal: cold, badly drained soil is fatal. Cutting should not begin until the plants are growing strongly. If three-year-old plants are set out in spring, cutting might perhaps begin in the spring of the next year. In autumn each season the tops are cut down, the beds cleared of weeds, and a mulch of well-decayed manure, garden compost, or seaweed is given over the whole of the bed. Agri-cultural salt, 2 oz. per sq. yd., is used in spring, and a little weak nitrate of soda may be used also, in liquid form, in the spring. When cutting the stems, as they are about four inches above the soil, push the knife well down, and carefully sever the one stalk only, 2 or 3 in. below the soil surface. Do not leave crowns exposed to late frosts—a protective covering of light litter is useful.

**Beans.**—Three types of bean are commonly grown in gardens. *Broad Beans* are the hardiest kind, and these can, in warm gardens with light, rich soil, be sown in late autumn to stand through the winter and provide an early crop. As a rule, however, little is gained by autumn sowing, and in most gardens the beans are sown in January or February, at the earliest opportunity when the soil is frost free. Beans can also be sown under glass in January to be set out later. Double rows are usually sown or planted, the beans being 6 in. apart in these rows, with 9 in. between the rows. At least 4 ft. should be allowed between two sets of double rows. The aim of the gardener should be to produce early rapid growth, since later sowings are often so badly attacked by the black dolphin fly that they are useless. In any case, the use of insecticide as a preventive measure, before any fly is seen, is advisable. Broad beans should be used either before the beans are formed in the pods, in which case the pods are cooked whole or cut into small pieces like runners, or when the beans have formed well but have not become tough. They should not have developed a black scar or eye, at this stage. Older beans are only suitable for soups and purées. If in spite of sprays, black fly appears on the growing tips of the plants, these should be pinched out at once, and a strong insecticide spray used immediately.

**Runner Beans are well known to everyone. If staked they form useful screens between gardens, or between parts of the same garden. They can also be grown without stakes, the tips being regularly pinched out as soon as the main stems, and later the side stems, begin to "run." This makes a bushy but very prolific growth, and is the method adopted by farmers in open fields. For the usual double row staked with crossed bean-poles, the seeds should be sown in early May, 3 in. deep, 9 in. apart in the rows, 1 ft. to 18 in. between the two rows. It is easiest to put in the two rows of seed, 1 ft. apart, and wait to drive in the bean-poles on the outer sides of the bean rows when the seeds have germinated. Good, rich soil is essential and moisture must be plentiful. Beans fail to set either because the weather is too dry—watering every evening overhead will solve this problem—**

or because the nights are too cold, and the flowers drop. Weather when no bees are flying is the sort of weather that ruins the bean crop.

**Dwarf or Climbing French Beans** form the third group of beans for the garden. These include the type of bean grown and ripened in the pod for use in winter. The dwarfs are sown in an open, sunny position on rich soil, in the first week of May, setting the seeds 3 in. deep, 6 in. apart in the row, and the rows 3 ft. apart. These are extremely tender and must be protected if they appear above the soil before the last frost. As with both broad and runner beans, it is possible to sow under glass and plant out later, but steady unchecked growth is to be preferred. Plants may, in a cool greenhouse, be grown out of season in large pots, but this necessitates the use of some heat to exclude frosts. The beans grown for winter use (Dutch brown, or Comtesse de Chambord) should be harvested in late September before the frosts. If not ripe at this time, the whole plants may be pulled up and hung in bunches in a dry shed until the pods are ripe enough for the beans to fall easily from them when they are held at the ends and twisted. It is worth note that all these beans, if well fed with liquid manure, will go on bearing almost indefinitely, until cut down by frosts. The runners and French beans are actually grown for three years on the same roots in warm climates, and it is only frost action that should put an end to their productivity here.

**Beetroot.**—From mid-April onwards, rows of round-rooted beet—Globe beet—can be sown on soil that has not been recently manured but is in good heart. A dressing of completely balanced fertiliser over the soil before it is raked for seed sowing will be useful if the ground is rather poor. If plenty of manure was worked in for a previous crop, a dressing of superphosphate just before sowing would be useful. Sow in drills 1 in. deep and thin to allow 1 ft. between the plants. If seeds are sown in the drills at 8-in. intervals, it will make the work of thinning easier: transplanting must not be done. Pull the roots as required for use, and make successional sowings at intervals of about a month from April to July. The long-rooted type of beet should only be grown for storage, and only in gardens where the soil is light and stone-free. In heavier soil the oval-rooted type is better for winter supplies. These winter roots should be sown in May or early June, and before being lifted and stored should be allowed to grow full sized but not over-large. Overgrown roots become woody and tough. In lifting and storing beet, take care not to injure the skin, and do not store any that are accidentally injured. Twist off the tops—do not cut them—an inch or two above the root. Pack the roots carefully into boxes, with slightly damp sand between the layers, or build them into clamps over straw, covered with more straw, in a shed, or with straw and a thick soil layer if clamps must be made in the open garden. Frost must not reach them or they will be useless.

**Sugar Beet** is a similar kind of plant to the red-rooted beet, but the skin and flesh are white. This makes an excellent vegetable for those who like it, and adds variety to the diet. Grow as ordinary beet. All beets should be kept free from weeds through the growing season, but great care should be taken over hoeing, as the small roots which feed the swollen rootstock are easily damaged by the use of the hoe too near the roots.

**Borecole.**—See Kale.

**Brassica.**—This is the generic name of a whole group of vegetables, more commonly known to gardeners as "greens." The group includes cabbages, cauliflowers, borecole or kale, Brussels sprouts, turnips, Couve tronchuda, and kohlrabi, each of which is dealt with under a separate heading. It is well to understand that a relationship exists between these crops, partly because they all need somewhat similar soil treatment, and partly because similar pests attack most of them, and can pass from one to the other. To group them together, and to move them all to a fresh site each year, is a good way to avoid much trouble over pests and diseases.

**Broccoli.**—Broccoli (of the large-flowered type) and cauliflower are the same thing to some cooks, but there is actually some considerable difference. Broccoli is thicker, coarser-leaved, greener in colour as compared with the pure creamy white of

a good cauliflower-head, and the plants are hardy enough to stand outdoors through the winter. Cauliflowers, on the other hand, need glass protection through the worst months of winter. A particular type of broccoli known as "Roscoff" is the kind grown in Devon and Cornwall to provide "cauliflowers" for the London market. Seed of broccoli should be sown in the nursery plot in April and May, or if good heads are wanted for autumn cutting, they may profitably be sown under glass in March or April. Harden off as early as possible, and when a few inches high, plant out into the nursery beds, 6 in. apart each way. Plants should be ready to set out in permanent positions in late May, June, or July, as ground becomes vacant. Plant them 2 ft. apart each way. Broccoli can follow an early crop of peas, potatoes, or other vegetables, and is best planted without deep digging after the early crop is cleared, as the plants prefer the soil to be rather consolidated. In addition to the cauliflower-headed type, there are purple and green sprouting broccoli, extremely hardy and very useful in the earliest months of the year. Treat these all in the same manner. Do not overfeed with nitrogenous fertiliser, as this encourages soft sappy growth that does not stand up to winter frosts, but a little general fertiliser can with advantage be used when the plants are growing well. Superphosphate, 1 oz. to each plant, and plenty of bonfire ash can be used before or soon after planting.

**Brussels Sprouts.**—To ensure hard, firm sprouts, sow the seed in the nursery plot in mid-March or as soon after as is practicable according to the weather. Sow very thinly along the rows, to avoid the need for pricking out, if possible; otherwise prick out to 6 in. apart. Transplant to permanent quarters in May or June, or when there is room on the plot; it is wise to leave the plants in the nursery bed until plenty of room can be provided, as they should not be set out closer than 3 ft. apart each way. Plants can sometimes be set out between the rows of late potatoes, after these have been finally earthed up. Draw the soil up towards the stems a month or six weeks after planting—or when the potato crop is lifted. Sprouts need liberal soil treatment for the best results, and nitro-chalk may be used as a soil dressing in summer if growth seems poor. Do not overfeed too late in the season. Cut off the lower leaves from each stem as they turn yellow, and cut the sprouts, as required, from the bottom first, leaving the top green tuft until all the sprouts have been picked. Sprouts should take thirty to forty weeks from sowing to maturity, and where garden space is available, a succession of sowings can be made from March until the middle of June, so as to lengthen the cropping period. Careful watch should be kept for the appearance of aphides, and the regular use of derris insecticide as a preventive is advised, especially for those who are growing for exhibition.

**Cabbage.**—Cabbages are extremely hardy. They are derived, with other brassicas, from the wild cabbage found on sea cliffs around these shores—a point worth remembering, because salt as an insecticide is an old and still useful remedy on the cabbage patch. Cabbages are sown at three times during the year—in March or April for summer use, in May or June for winter, and at the end of July or beginning of August for spring cabbages. Sowing is always done in a nursery plot, not on the main bed where the plants will mature. Preparation of the soil in the nursery seed-bed is important. To burn off the top weeds and rough growth and then sow cabbages is an old practice which is still carried out in some districts. In any case, fine soil, burnt earth, wood ashes, and some lime should be used in preparing the seed-bed, since this will produce strong, sturdy plants. Prick out as soon as possible, and set the plants out in permanent positions as soon as they are reasonably well grown. For spring cabbage, sowings should be made at the end of July in northern gardens, but not until the first week in August in the south. If sown too early, the plants are likely to bolt instead of making hearts. As a rule these plants are set out 9 in. apart in the rows, leaving 18 in. between the rows. They can be set out 9 in. apart each way if space is precious. When greenstuff is short in late winter, every alternate plant can be cut, leaving only one plant

every 18 in. to heart up, the ones removed being serviceable as greens. If the ground in which these cabbages are set out is in good heart, they should need no attention beyond drawing a little soil up against the stems before the worst frosts come along. This may prevent frost loosening them in the ground. In March, cabbage seed will again be sown in the nursery plot, or, if the weather is bad and a frame is available, it can be sown in the frame in boxes. Prick out and transplant by the ordinary way. This sowing of cabbage will grow rapidly as the warm weather approaches, and it can therefore be set out in good rich soil. Nitro-chalk is a fine stimulant if one is required. The distance apart for the seedlings varies quite a lot according to the type. Coleworts need no more than a foot of space; some cabbages will need 2 ft. each way. The owner of a small garden is advised not to grow the largest types unless the family specially likes them, as the smaller ones are often more useful. In late April, May, or June as convenient, a further sowing of Christmas Drumhead, or January King cabbages is useful. These will come in, as their names suggest, in mid-winter. A site for these sowings will generally be found where potatoes have been lifted, or early peas, broad beans, etc., have been cleared. Cultivation is similar to that given to earlier sowings, except that if a stimulant is needed, this should not be given too late in the season, and should be a general, balanced mixture such as the "Growmore" fertiliser of war-time production. Too much sappy growth in the late autumn is to be avoided. Red cabbages are grown in just the same way as other cabbages, but they take longer to mature. They are usually sown in August, and transplanted 6 in. apart in a reserve bed, where they remain through the winter. In early spring they can be set out 18 in. apart each way. They will not mature until late summer. Weak doses of liquid fertiliser given through the hot weather will increase their size. It is worth noting that all cabbages, cut off as near the top of the stem as practicable, will make new growth if left in the ground. A common practice with winter standing cabbages is to cut across the stem top twice, in opposite directions, before leaving it, and this results in bunches of young leaves developing at this point. These young leaves are very useful either as greens for the table, or as food for rabbits, etc.

*Savoy cabbages* are sown in May and transplanted in July or early August to beds that have been dressed with superphosphate and wood ash. This should help to produce hardy plants that will be improved by a touch of frost. Set the seedlings 18 in. to 2 ft. apart each way, and remove yellow leaves in autumn and winter. Savoys are among the hardest of all crops, and should, for this reason, find a small place in every garden, in case the winter should prove exceptionally hard.

*Cardoon*.—Seeds should be sown in April or May, where the plants are to mature. The best method is to open trenches, 18 in. wide and 1 ft. deep, and work in 3 in. of good manure in the bottom soil. Then add a second 3 in. of fine, sifted soil. When the weather is favourable for seed sowing, dibble in three seeds in a group, every 18 in. along the trench bottom and water well. Cover each set of seeds with an inverted flower-pot until the seedlings are visible; then thin out to leave only one strong seedling at each station. Leafy branches laid across the top of the trench will protect from possible late frosts. Draw a little earth up against the plants once or twice during the growing season, and make sure the water supply is maintained. In autumn, about September, on a dry day, gather the inner leaf stalks together and tie them round the stem with raffia; then, especially if plants are being grown for show, wind a strip of brown paper round the stems from base to the top, leaving only the tips visible. Bind hay round the lower part, and set a light stake to each plant. Then earth up in two or three operations as for celery, and leave for at least four weeks, or until wanted. Some loose, dry litter over the tops will protect them should frosts arrive. Only the blanched heart is used by the cook.

*Carrot*.—The wild carrot is well known in many parts of Britain and the Continent. Garden carrots are grown as annuals only, that is, they must be raised from seed and used during the first

season (or in the winter following). Light soil, well drained, enriched with decayed organic material, but not with fresh manure, is right for carrots. If the garden soil is naturally heavy clay some burnt earth, sand or clean grit, wood ash, and air-slaked lime will help to bring it into the condition needed for carrot cultivation. Preferably, however, the type of carrot grown on such unfavourable soil should be the short stump-rooted varieties only. If long-rooted carrots are wanted, and the soil is stony and difficult, the site for each root should be prepared by making deep holes with a dibber, filling in prepared, sifted soil, and sowing one or two seeds only at each station. As soon as the seeds germinate, each group will be reduced to one, and in this way, good exhibition carrots may be grown even on a clay soil. The hole prepared should be at least 3 ft. deep, and a crowbar may be a better tool than a dibber.

For normal culture, a drill should be drawn  $\frac{1}{2}$  in. deep, and rows should be 1 ft. apart. Cover the seed lightly, and on clay soils, particularly, do not water until the seedlings are above the soil. Carrot seed sometimes fails to germinate if a hard crust of consolidated clay forms over the seed. Thin out to 4 in. apart (or 6-8 in. for large roots) as soon as possible, but before thinning, water well and make sure that the soil is pressed back firmly, as looseness in the soil is an encouragement to the carrot fly. For the same reason, remove the thinnings, as the odour of these also encourages the fly. Carrots should be sown for succession, and the first row can be sown in early April, later ones at intervals of four weeks until the end of July. Until late in June every sowing should be dressed with naphthalene, at the rate of 1 oz. per yd. run, to discourage the flies. It is seldom that late sowings are affected by the pests. The late sowings will provide carrots for storing in winter. These should be lifted in October, or earlier if they are well grown, as it is better to store them early than to have them coarsened by being left too long in the ground. Cut off the carrot tops  $\frac{1}{2}$  in. from the root, and store the roots in slightly damp sand in boxes, or in clamps. A convenient method in storing carrots in a shed is to lay down a thick layer of straw over the concrete floor, pile the carrots neatly on this, tops outwards, with sand between every layer, and cover the pile with sacks or more straw. Frame cultivation is often practised for the sake of early and late carrots. For this a mild hot-bed is desirable in January, and such suitable forcing varieties as Amsterdam Forcing, or Early Gem, or Early Nantes should be chosen. These same quick-growing varieties can be sown in July for young carrots in late summer and autumn, either in a frame, or on a warm border.

*Catch Crops*.—This is the term used for crops which are interplanted among other crops, so as to avoid waste space in the vegetable garden. For instance, between rows of broad beans, lines of radish might be sown. The radishes will be pulled before the beans are large enough to need the whole of the allotted space. Similar interplantings and sowings are practised as occasion arises—lettuces set out between rows of celery, or round the edge of a mound prepared for marrows; and so on. Ground must be in good heart to allow for success with close planting of this kind, but in a small garden the correct use of catch crops will double the amount of produce grown on each area.

*Cauliflower*.—As with most of the brassicas, cauliflowers vary considerably in quality, and it pays always to buy good seed from a seedsman who has a reputation. Deep, rich loam is essential for good growth, and land should be well manured if there is any doubt about its fertility. A dressing of garden fertiliser of a balanced kind should be given a week before planting out, or along the rows when the seedlings have become established. Lime in the soil is also important, and when the digging has been done, a top dressing of air-slaked lime should be applied and left to wash down for a week or two, or longer, unless the top soil is naturally chalky. Sow the seeds in a cold frame or glasshouse, in January (if gentle heat can be given) or in February or March as circumstances dictate. Outdoor sowings can be made in March or April on a warm border, to produce heads in late autumn. Prick off as early as possible—those under glass into boxes of soil to stand in the frame, and to be

hardened off as soon as practicable. Aim to produce strong, short-jointed seedlings that have not become drawn and leggy. Plant out the first sowings in April, and others as they are ready. Set the plants from 18 to 30 in. apart each way, according to the variety. Keep the hoe going constantly through the summer and make sure that the plants do not suffer from lack of soil moisture. A small quantity of nitrate of soda or sulphate of ammonia added to the water (allow about 1 oz. to a square yard of soil) used after ordinary watering once or twice after the curds have begun to form will increase the size and quality of the cauliflowers. Gardeners who can use cold frames can make sowings of a variety such as Autumn Giant or All the Year Round in a frame in autumn. These will be pricked out as soon as possible, and wintered in the frame.

Water freely all summer, and remove side shoots if they appear. In November the roots may be lifted and stored as other root crops, or they may be left in the ground and used from there as required. As frost may damage them, it is usually best to lift and store.

**Celery.**—Celery is usually grown in trenches, which allow for copious waterings and also for easy blanching of the stems when they are well grown. There are certain strains<sup>2</sup> of celery, grown for the first early supplies, which are self-blanching, and these can be grown on the flat, with similar treatment to that suggested above for celeriac. For ordinary varieties seed should be sown about the middle of February or not later than March, in a temperature of 60–65° F. Cover the seed with the finest possible dust of soil, as if covered too deeply, the seed fails to germinate.

**TWO METHODS OF BLANCHING CELERY.**—(a) By means of paper collars tied tightly round the stem to exclude light; (b) by means of earthing up the surrounding soil in three stages. In both cases the leaves are tied with raffia before blanching.

These autumn sowings are also useful for planting in beds in a greenhouse, where it is possible for them to be grown to maturity. In most gardens, however, it is better to rely on broccoli for the winter crop. If cauliflowers are ready for use in late autumn, and may be damaged by frosts, they can be protected by having a leaf or two broken over the curd; or they can be lifted with a large digging fork sufficiently to lay them over on one side, and then covered with loose straw until they are wanted for table.

**Celeriac.**—A plant allied to the common celery, and worthy of more attention than it receives at the hands of gardeners generally. In the case of celeriac, the part eaten is the swollen root, not the leaf stalks which are hollow and bitter to the taste. Celeriac can be grown in gardens where celery is difficult, and it can be used in the same way as other root crops, that is boiled (chopped or sliced) or grated into salads. The flavour is similar to that of celery. Celeriac can be grown like celery, but less preparation of the ground is demanded, as celeriac will grow on the flat, or in very shallow depressions such as are prepared for peas, made thus merely to facilitate watering. Sow the seed under glass in March, in temperature 60–65° F. Cover with only a very fine dust of soil, and as soon as the seedlings have made three leaves, prick them out into boxes, 2 in. apart each way. Gradually reduce the temperature after this, and let the plants be hardened off by the end of May. Draw shallow drills, 18 in. apart, and set the plants 1 ft. apart along these drills. Dust the foliage with soot at planting time, and at weekly intervals afterwards, to discourage the celery fly, which otherwise lays eggs in the leaves and produces the same silvery-brown tunnelling that occur on celery and on chrysanthemums.

Keep the seed-pan damp, and the seedlings should appear in three weeks. When three leaves have formed, prick out the seedlings into boxes filled with compost that contains sifted manure or garden compost and enough sand to allow for drainage. Allow 3 in. between the plants at this stage, and use boxes that are at least 4 in. deep, so that the plants can grow on and become sturdy and strong by May or June, when planting out begins. Meanwhile prepare trenches by excavating in early spring to a depth of 1 ft. Clear all the top soil from the trench, and fork the bottom well. Then put in a layer of 6 in. of good farm manure or well-made garden compost. Gardeners near the sea could use rotted seaweed for this purpose. Cover the manure with 4 in. of good top soil, and dust air-slaked lime over the surface. The soil excavated from the trenches should be neatly piled in square-topped ridges between the trenches which should be 3–4 ft. apart. Lettuces sown or planted out on these flat-topped ridges will mature before any earthing up is done, and so prevent a waste of garden space. If the trenches are prepared in early spring, they will have had time to settle before planting is done in May. Make up the trench soil, if it has settled too much, so that the plants are about 3 in. below the surrounding soil level. Water the plants in the boxes a short time before planting them out with a trowel, so that there is the least possible root disturbance. Remove any suckers that are present, and set the plants firmly in the soil, 10 in. apart down the centre of the trench, or, if preferred, set them in a double row, staggered, 1 ft. apart. Water well, and dust with soot at once: the celery fly is attracted by the odour of the plants, which is strong when the plants have recently been handled, and soot helps to disguise

this odour. Soot should be used again every week, to discourage the fly, or derris insecticide may be used if an attack occurs and the plants are suffering severely. The fly lays eggs in the leaves, and the maggots that hatch out tunnel between the leaf surfaces. If brownish marks are seen on the leaves, pinch each between thumb and finger, to destroy the maggot that is inside. Watch also for Leaf Spot, and spray with Bordeaux mixture if necessary. Water frequently if the summer is dry, and when the leaf stalks are almost fully grown, not before, begin to earth up. This is done in stages. At the first earthing, the side growths, if any, are removed, and the leaf stems are carefully drawn together with soft tying material near the top tuft of leaves. About 4 in. of soil is then drawn from the trench sides to cover the lowest part of the stems. If plants are being grown for exhibition, a brown-paper collar should be tied round the whole stalks before earthing. (Collars of this type are useful for the self-blanching types.) Every week after the first earthing a little more soil may be drawn up towards the plants, until a bank of well-packed, but not solid, soil covers all the plant with the exception of a tuft of green leaves. This should happen before the arrival of frosts, and if hard weather comes, light litter should cover the whole row. Should slugs be seen at the time of earthing up, or earlier, a slug-killer should be used along the row, as slugs can take a heavy toll of the celery crop.

**Chards.**—When the crop of globe artichokes has been cut, the plants are cut back. New growths form and these, if bound with straw when they are about 2 ft. high, will become blanched, and six weeks later they can be used as a vegetable. These young, blanched growths are called "chards."

**Chervil (Parsley-leaved, or Fern-leaved).**—These are annual herbs which should be sown in March, on well-manured ground. Sow in drills 10 in. apart, and thin to 6 in. apart in the rows. Further sowings can be made through the summer, and August sowings will stand the winter if in a mild, sunny situation. Some protection may be necessary, and frame culture is good if a frame can be spared. These herbs are used in salads and soups.

**Chicory.**—This crop is grown for the sake of young, blanched growths, called "chicons," which are used in winter salads, and also are cooked to be eaten with white sauce. Seeds are sown in drills 1 ft. apart, in May or late April. Thin out to 8 in. apart when the seedlings are 1 in. high, so that strong plants are obtained for forcing later. If preferred a part of the seedlings can be left unthinned, and the young, green leaves cut for use in the salad bowl. The plants selected for forcing are grown on until October or November. They are then lifted with a large digging fork, the larger leaves cut off, and the roots pruned a little. They are then planted in deep boxes half filled with light soil, and light litter is used as a covering over the soil surface. In this condition they are stood in a warm part of the greenhouse, or other sheltered place, where the chicons will gradually develop. Light must be rigidly excluded from them to obtain the creamy palatable young growth that is desired. About 6 in. of top growth should be present when the chicons are removed. It is possible to force chicory in an ordinary light greenhouse if the boxes are filled to the brim with clean sand after the plates are put into the soil. When the chicons begin to grow through this sand layer (which should be 6 in. deep) they are ready to cut.

**Chives.**—These are like very small onions, and are grown in grass-like clumps, usually as border edgings to a vegetable or herb garden. They are excellent plants for window-boxes and town gardens. They are planted in March, about 6-8 in. apart, and when the clusters become very large, they can be lifted and divided either in autumn or spring. The leaves are the part used, and these should be snipped off with scissors as wanted for salads or soups.

**Colewort.**—Cabbage in the young unhearted stage. The Dorsetshire Kale, now almost extinct, was also called colewort.

**Corn Salad.**—Also called Lamb's Lettuce, is a weed of the cornfields, but is often grown for use as winter and early spring salad. Sow thinly in lines from August to October, or broadcast over a patch of rich soil. Pull the whole plant as leaves are wanted for use. This salad is said to

be best used alone, with vinegar and bread and butter, but it also helps the winter mixed-salad bowl.

**Couve Tronchuda (also called Portugal Cabbage).**—A crop for large kitchen gardens only. Sow in March and plant out on ground that was richly manured in winter as soon as the plants are large enough to handle. Set them 2-3 ft. apart each way. Cook the midrib of the outer leaves, first, and the heart later as cabbage. This vegetable is grown for large exhibition classes, but is rarely thought suitable for the ordinary small garden.

**Cress.**—Garden cress is an annual grown very rapidly from seed and harvested when only the seed leaves have developed. It is a crop that can be grown by everyone, since it is possible to grow it well on damp flannel in an ordinary window. For general purposes it should be sown every two or three weeks, all the year round, in boxes of light, sandy soil. The soil should be moist, and the seed sown thickly, covered with a sheet of brown paper, and kept moist and warm. Do not cover the seed; merely press it well down into the soil. Germination may take place in two or three days, and from that time full light should be allowed. If well watered at sowing time, no further water may be needed, but boxes must never dry out entirely.

**Cucumber.**—The cucumber of the shops is a plant grown under glass. Ridge cucumbers, which are somewhat prickly on the outside, and smaller, may be grown outdoors in summer, and if well grown, are as useful in the salad bowl as the indoor type. For glasshouse culture, sow seeds soon after Christmas, a single seed in a 3-in. pot of sandy loam over good drainage. Cover seed  $\frac{1}{2}$  in. deep. Water with tepid water and plunge the pots into a manure bed, or into damp fibre over hot pipes. Move the pots near the glass when the seedlings appear, unless the weather is very frosty. Keep the temperature up to 75° or 85° F. Pot on regularly, avoiding any check to growth, potting the young seedling right up to the seed leaves in the prepared compost, which should be rather rich and light. Do not pot too firmly. Plant out into beds on the greenhouse floor. Ridge-shaped beds are most common, the bed being 2 $\frac{1}{2}$  ft. across at the base and 18 in. high. Or the plants can be set into mounds of soil on the greenhouse stage, using about half a barrow load of soil to a plant. Support the growth with a light cane, and train the plants later to wires stretched horizontally along the roof, 9 in. apart and 9 in. away from the glass. A single stem, with no side growths is formed up to the first wire, and side stems then trained each way along the horizontal wires. Stop the main stem when it reaches the top wire; stop the side growths just beyond a second leaf from the first female flower on each. Cut away tendrils and tie in laterals and sub-laterals every few days, and remove all male flowers as they appear, otherwise the fruits will be shapeless and seedy. Cucumbers need no ventilation as a rule, but should be syringed with tepid water twice a day, wetting the stages and floors as well as the plants. Shading over the glass is usually necessary to prevent scorching. Just before the withered blossom is ready to drop, the fruits should be gathered: cut them carefully and if they are not wanted at once for the table, set the cut end in water and they will keep for several days in perfect condition. Cucumbers can also be grown in frames. For this make a hot-bed of leaves, manure, and light soil in January or February, and sow the seeds as soon as the beds are hot enough, standing the pots on boards raised above the bed on bricks. By the time the seedlings are ready to plant out in the hot-bed itself, this will have dropped in temperature sufficiently to allow for safe planting. Peg down young growths from time to time, and do not let too many fruits develop at once.

**Ridge Cucumbers** are raised from seed sown under glass in the same way as the other type of cucumber is raised. A cold frame, or cloche, is sufficient protection for these seeds, however, if no heat is available. Plant out towards the end of May, on ridges of good, well-manured soil, or on flat sites in a border of rich soil. The plants need sunshine, but must be kept well supplied with water at the roots. In a sunless season they often fail to develop a sufficient number of fruits.

**Drill.**—A small trench, usually V-shaped, but sometimes flat-bottomed, drawn with hoe or rake

or pointed stick, to take seeds. The usual practice is to stretch a line of string across a plot first, and then, using the most suitable tool according to the depth of drill required, to draw the tool alongside the line, so that a straight drill is obtained. Covering the seed in a shallow drill is easily done either by passing the back of the rake along the row after sowing, or by "jumping" the rake, held vertically, along the row.

**Endive.**—There are two types of this popular salad plant—cut-leaved, which is most common in the shops, and round-leaved or Batavian Endive which is extremely hardy. To cultivate either type, sow seeds in April in lines about 18 in. apart, and thin out to leave each plant 15 in. of space. Sow again in June and July, for succession, and again in August and September for winter supplies. Plenty of moisture and a good, rich soil are needed, but otherwise little special care is needed beyond keeping down the weeds. Plants are blanched before use, otherwise the leaves are too bitter to be palatable. In summer or autumn this can be done either by tying the leaves loosely together so that light is excluded from the heart, or by inverting a large flower-pot over each plant, with a flat stone over the hole to exclude light. In winter the same method can be adopted provided frost can also be kept out, and this may be done by piling light, loose litter over the inverted pot. Alternatively, plants can be carefully lifted in October, with a trowel, and replanted close together in a spare frame, and these plants can be blanched when fully grown by throwing mats over the frames. Or the plants can be lifted and packed into wooden boxes of soil, if they are fully grown, and the boxes stood for a few weeks in a dark cellar or shed. The Batavian or round-leaved endive is an excellent plant for a town window-box: its leaves curl over the front edge in decorative fashion—until they are needed for the salad bowl.

**Fennel.**—A useful culinary herb for sauces, pickling, salads, etc. Blanched stems may also be cooked in the same way as celery. Sow in drills 2 ft. apart, in good, rich soil. Thin out to 18 in. apart, to allow for full development. The plants are perennial and can be increased by root division in spring. Florentine fennel—the kind with the thick stems that are cooked and eaten, is best treated as an annual, sown in May, and thinned to 1 ft. apart.

**Garlic.**—A little of this goes a long way, in the garden as in cooking. But a few "cloves" planted in February, 9 in. apart, will supply sufficient for most families, and may prove very useful for occasional salads and for pickling. Treat the crop as shallots, *i.e.*, keep down weeds, feed with a pinch of nitrate of soda in water, necessary during summer, and when the growth is complete, lift the plants, let them dry in the sun for a day or two, and then sort over and store in a cool, frost-proof shed. Save enough of the best cloves for replanting in the following February. Rich, friable soil suits the plants best, and each clove should be just covered with this at planting time. If many are to be grown, draw a drill 2 in. deep to receive them.

**Greens.**—See Brassica.

**Herbs.**—Culinary and aromatic herbs are plants that can give character to a garden as well as to the housewife's table. If it is possible, a separate herb garden with individual beds each containing one or two different herbs can well be made; or a decorative border under a south fence, separated from the main vegetable plot by a path, could be planted with groups of herbs arranged informally as plants in an ordinary mixed flower border. Many herbs have fine showy flowers as well as fragrant foliage, and are worthy of a prominent position in the garden picture. Some of them are annuals, such as anise (seeds of this are *aniseed*), basil, chervil, coriander, dill, Florence fennel, parsley, purslane, summer savory; others are perennial, and this group includes borage, caraway, chives, fennel, garlic, horse-radish, mint, pennyroyal, marjoram, rosemary, rue, sage, tansy, tarragon and thyme. Among medicinal herbs are those grown simply for their fragrance can be included lavender, chamomile (anthemism), horehound, hyssop, and pot marigold—the last three from seed and others from roots or cuttings. With all these common herbs from which to select, it is

obvious that a complete picture can be made, and the grouping of herbs in a single part of the garden makes both for convenience and interest. Where a formal design is contemplated, the introduction of a central feature such as a bird bath, table, or sundial is particularly appropriate. Paths through the herb garden are also best of some material that assists the old-time character of the whole—brick, tile and brick, cobble and paving, etc., rather than paths of too formal appearance. (For cultivation of the most common of the herbs mentioned, see other references.)

**Horse-radish.**—The ground should be deeply dug in autumn, and good manure or garden compost should be buried well down, to feed the roots as they penetrate into the sub-soil. If the soil is of clay, work in ash (finely sifted, not coarse coal ash), road grit, sand, strawy manure, and so on, to bring it into friable condition. Plant straight roots, each with crown, putting this crown 6 in. below the surface. A long dibber is a good tool for planting, as its use encourages the roots to go down well into the ground. About a foot from root to root is sufficient space, and if weeds are kept down, no further treatment should be needed all the season. Lift the roots in winter, preferably from a half or a third of the plot only. Select pieces for replanting, and use the remainder. Manure the ground before replanting in February, and the next season leave these roots undisturbed, and lift from another part of the plot. Continue this practice so that the roots have a long season of growth before they are wanted for use, always using added manure when the ground is being prepared for the new plantation. It is not wise to change the ground—lifting a part and replanting in the same part is better, as horse-radish roots penetrate very deeply, and parts of the roots become left in the ground. This makes it difficult to keep horse-radish under control if it is grown among other vegetables.

**Kale.**—A biennial of the brassica family, grown as an annual in the garden. It is the hardiest of all the "greens," and should for this reason be grown in every garden because of its capacity for coming through the worst winters. Even when it becomes deadened by weeks of frost and snow, fresh green leaves quickly grow again, and are available for use in a short time. Sow in April or May, and plant out into winter quarters as soon as convenient. There are many types of kale, and in a large garden several varieties should be grown. In small gardens it may be better to sow only a few seeds of the Hungry Gap Kale, which is a variety that must be sown in June where it is to mature. All kales will take about 2 ft. of space each way for development.

**Kohl Rabi.**—A vegetable with a swollen-stem base that in flavour and appearance is something between a turnip and a cabbage. Seeds can be sown in April, where they are to mature, and thinned to 1 ft. apart, or sown in a nursery bed and transplanted 1 ft. apart. The swollen stem or "root" should be harvested and used when not much bigger than a tennis ball, or it becomes coarse. If not used at once, the crop should be stored in the same way as turnips.

**Lamb's Lettuce.**—See Corn Salad.

**Leeks.**—By those who have no frames or glass-houses, leeks should be sown in a sheltered nursery bed in March. Sow in lines about 8 in. apart, and sow as thinly as possible to avoid the need for pricking out. Keep the hoe going between the lines, and prevent weeds from choking the young plants. The soil should be sufficiently rich to encourage strong growth, and by May or June, when the leeks are set out in permanent quarters, they should be 4-5 in. across at the soil level. If the seedlings come up thickly, they can be pricked out to 4 in. apart in the nursery bed, but too many moves are not welcomed by the plants. When the seedlings are large enough to be set out finally, they are planted 1 ft. apart in rows 18 in. apart. The best way is to stretch a garden line across the plot; then, with a dibber, make holes 9 in. deep at intervals of 1 ft. along this line. Take each seedling, trim off a tiny tip of the green leaf, and drop the seedling in the hole. The leaf tip should be an inch or two above the ground. Do not use more soil, or firm the plants in the ground, but water well after all the plants are in, so that they get a root-hold at the bottoms of the holes. Feed occasionally, after rain, with nitrate of soda or

sulphate of ammonia, 1 oz. in a gallon of water. In September draw a little more earth up against the plants, which should be thick and strong by this time. Leeks are hardy, and can remain in the ground in winter, to be used as required.

**Lettuce.**—Lettuces are of two main types—*Cos* lettuces which have long, straight leaves that either curl inward naturally so that the heart of the plant becomes more or less blanched, or are tied in by the gardener to produce the same result; and *Cabbage* lettuces, which are broad and spreading, with round hearts like those of cabbages. *Cos* lettuces are a summer crop, cabbage lettuces are grown to supply salads all the year round, the latest sowings being made in October in a frame, or in September outdoors, and the earliest in January under glass or in

ONIONS keep best in store when made into ropes as shown above. Soft twine is used. The ropes of onions are hung in a dry, frost-proof shed.

March outdoors. Sow the seeds thinly in lines 8 in. apart, and thin out or transplant so that the plants ultimately stand 9-15 in. apart, according to the variety. Quick, unchecked growth is the secret of success. Any sudden change of temperature, dryness at the roots, damage in transplanting, or other check will result in toughness, and very slow growth, such as that taking place in mid-winter, will also cause toughness. Frame lettuces are more tender than others, with the exception of those grown in warm, showery weather, and the aim of the gardener must always be to provide warmth, moisture, and food in abundance. Bone-meal worked into the soil before planting helps lettuces, and nitrate of soda or sulphate of ammonia used in liquid form during growth is also helpful. Small garden owners should make sure of successional supplies by sowing at fortnightly intervals, a little at a time, instead of sowing a whole packet of seeds all at once.

**Maize (Sweet Corn).**—Gardeners should distinguish between the types of maize (*Zea mays*) grown to provide corn for poultry, and those types that are grown to provide sweet corn for the table. Of these latter types, some are specially suited to British gardens, and these are listed in catalogues. The seeds should be sown under glass, in slight heat, in April, hardened off in May and planted out at the end of this month, when frosts are past. Plant 1 ft. apart with 2-3 ft. between the rows. Deep, rich, moist soil is needed for good cultivation. Gather the cobs when the corn is still milky, otherwise it is inferior when cooked. The best cobs are those that are grown very rapidly on good fertile soil in a warm situation.

**Marjoram.**—Hardy perennials which can be raised from seed; or roots can be divided in spring or autumn. They like warm, dry soil and full sunshine. Plant 18 in. apart in the herb garden.

**Marrow.**—Vegetable marrows, pumpkins, and gourds are all cultivated in the same manner. All need plenty of water and plenty of plant food of a balanced nature. They must also have a good deal of sunshine. Sow the seeds, singly, in thumb pots under glass in March or April, or sow outdoors where they are to grow, in April. Frost will damage the young plants, and if they are sown outside, they must be covered over at night should they appear above the ground when frosts are possible. An old hot-bed is an ideal place for marrows to be planted out at the end of May, but they will also grow in an ordinary border, on a flat site. Seed two years old is

generally preferred for sowing: new seeds produce plants that are liable to grow more leaf than flower. Do not plant too firmly in sticky soil: marrows like crumbly decaying manure of porous nature.

**Mint.**—An essential herb for every garden. Plant any piece of root in any soil that can be kept moist, and mint will grow. It is best to plant pieces of root in a special isolated bed, for mint rapidly runs through the soil, and becomes a weed among other plants. For winter use a few pieces of root can be planted in a warm, sheltered bed, or in a frame if one is available, in autumn.

**Mushrooms.**—Mushrooms can be cultivated by anyone who can obtain fresh stable manure. Without this, cultivation is not an all-the-year-round success. A warm, damp cellar, disused air-raid shelter, or dark shed is suitable for mushroom culture. Beds are made up of fresh manure, with leaves, and good loam, and when the temperature has dropped sufficiently, pieces of spawn are inserted. The beds are covered with soil, and in a few weeks the mushrooms appear. Temperature at spawning time should be about 75° F. Modern mushroom culture is made more certain by the production of high-quality clean-culture spawn, and this is sold with detailed instructions for the preparation and spawning of the beds. For ordinary outdoor culture, pieces of spawn are buried under turf, and left to develop when the weather and temperature allow. Spawning of this kind should be done only in late spring or early summer when there is reasonable prospect of the temperature keeping above 50° F. for a few weeks after spawning. Mushrooms only appear on grass in "mushroom weather," that is, when the air is warm and moist and the soil in similar condition.

**Mustard.**—This is grown in exactly the same way as cress (which see,) but the crop is ready two or three days sooner. If the mustard and cress are to be used together, therefore, the mustard seed should be sown two or three days after the cress is sown. In both cases it is the seed leaves which are cut to use in salads. Mustard seed is also sown for green manuring, that is, seeds are sown broadcast over land that can lie idle for a time. When the plants are well grown, but not in flower, they are dug in to help to provide humus in the soil.

**Onions.**—Onions, more than most vegetables, respond to good cultivation. There are three sowing times for onions. They can be sown in August or September, when the last season's crop is lifted. These onions should produce the giants of the show bench, since they have a full twelve months in which to grow to maturity. There is some danger of bolting, due to the fact that the plants may receive a check in winter, or when and if they are transplanted. The usual practice is to sow thinly in a line across the vegetable garden, and to plant out in March in permanent positions 1 ft. apart in rows 10 in. apart. Some growers merely thin out in spring, to allow sufficient space between the seedlings. Seed can also be sown under glass in January or February if some heat can be provided, or sown outdoors in March. Seedlings raised in deep boxes of good soil must be transplanted with care, so that roots are not damaged, in April. The advantages of autumn-sown onions is that they are less liable to attacks from the onion fly: the disadvantage is a greater tendency to bolt. Dusting the rows with calomel dust when the seedlings are 1 in. high, and again when they are set out permanently will control the onion fly. Frequent dustings of soot are also useful, and regular dressings of sulphate of ammonia or nitrate of soda during the growing season (but not later than July) will assist in producing giant bulbs. In early August the onion tops should be bent over towards the north, to allow sun to ripen the bulbs, and later the bulbs should be lifted with a fork, and allowed to dry in the sun for a few days before being roped. Giant bulbs for exhibition should have rough, damaged outer skins carefully removed, and then should be laid out in the sun to produce the fine, silky even texture that will catch the judge's eye.

**Parsley.**—Sow parsley in March and September each year, to keep up a constant succession of good, young plants producing curled foliage of high quality. Never allow plants to send up flower stems, unless seed is desired. Sow thinly,

in lines 8 in. apart if several rows are wanted. Parsley makes fine border edgings to vegetable or herb plots, and plants for this purpose should be set out (or thinned to) 4-6 in. apart.

**Parsnip.**—A long season of growth is required by parsnips, and ground should be prepared in winter for seed sowing in February or as soon after as weather permits. Parsnips like a deep, friable loam. If they must be grown in sticky clay or stony ground, it will pay to practise this method of cultivation: Prepare the soil in the ordinary way in winter. Then, when sowing time comes, prepare a barrow-load of good potting soil, i.e., a mixture of loam, sand, and decayed manure, all passed through a  $\frac{1}{2}$ -in.-mesh garden sieve. A little balanced fertiliser could be added,

**CLAMPING POTATOES.**—Where too many potatoes are grown for indoor storage they can be clamped outdoors. A straw chimney is important to admit ventilation.

say a  $\frac{1}{2}$  lb. to a barrow-load. Stretch a garden line across the plot, and with a crowbar or long dibber make holes at intervals of 15 in. along this line. If more than one row is to be grown, allow 18 in. between the rows. Fill each deep hole with the sifted mixture from the barrow, and sow three parsnip seeds in each. When the seedlings germinate, thin to leave only the strongest at each station. This procedure will ensure good, long, straight roots. For ordinary culture on congenial soil, sow in drills 1 in. deep, and thin out to 12-15 in. apart. Harvest in late autumn, or leave to be used as wanted, if the ground is not required for other purposes. Light litter over unharvested rows will keep off some frost and allow for ease in lifting.

**Peas.**—Peas can be sown at any time from November onwards when the soil is in good condition and frost free. As a rule nothing is gained by sowing before about the end of February, however. Sowing can continue until June, but the earliest and also the latest sowings should both be of "early" varieties, that is, varieties that mature quickly. These are usually the dwarfs, which are more suitable for most gardens than the tall kinds, as little or no staking is needed. For general purposes, take out a shallow trench in well-dug and richly manured ground. This trench can be of spade width and about 4 in. deep. Scatter seeds thinly along the trench bottom, about 3 or 4 in. apart, or space them carefully by hand in a double or treble row. Cover with 2 or 3 in. of fine soil—the deeper covering for sowings made late, that are more likely to dry out. Seed can be soaked, if desired, for a few hours prior to sowing. Coating with paraffin and red lead is also practised by some gardeners, to keep away birds and mice. Set small twigs for support of the young growth at once, and later, if the variety is a tall one, put in pea-sticks. A dusting of lime along the sides of the pea rows is of assistance. Peas need good soil, but actually leave the ground rich in nitrates after they have gone if the tops are cut off and the roots left undisturbed, since the roots have the power to fix nitrates in the soil. It is a common, and wise practice to cut off the tops, rake them away, and then set out winter greens on the site without any further preparation of the ground, when the pea crop has been gathered. In this way the greens benefit from the nitrogen left in the pea roots.

**Potato.**—Potatoes are richer in food than any other garden vegetable, yet they are not always a wise choice for a garden crop. They take a considerable amount of room and can more economically be grown on farms where machinery can be employed at various stages. At the same time it must be acknowledged that there is nothing in any shop so good as home-grown new potatoes,

and that the varieties commonly chosen for farm cultivation are those that crop heavily, irrespective of their flavour. A few rows of early potatoes are therefore suggested as a useful crop even in a small vegetable garden, and production of the whole family's needs in this direction is recommended where it seems practicable. The potato is grown from so-called "seed"—actually middle-sized tubers, selected from the previous season's crop. Storage of these tubers through the winter is important. The best way, if home-grown tubers are used, is to put the selected ones (weighing about 2½ oz.) in shallow trays, rose end (where the eyes congregate) upwards, immediately they are lifted and dried. Keep them in a light, airy shed, where frost will not penetrate, and where mice and rats will not make meals off them. In the early months of the year these will begin to sprout, and will make short, thick growths that are ideal from the cultural point of view. If potatoes are purchased, they should be set in the sprouting trays in this manner as soon as they are received from the growers. The first earlies will be planted in March or early April, according to the locality and the weather. It is important that the top growth should not be subjected to frosts, and if potatoes are planted early, and come rapidly through the soil, more soil should be drawn up from between the rows to cover the growth at once, so that night frosts will do no harm. Early potatoes are set 1 ft. apart in the rows with 2 ft. from row to row: late-crop potatoes need twice this space for development in good soil. If the ground is poor and hungry, a dressing of good manure along the drills that are opened, 6 in. deep, at planting time, will help the crop: or balanced fertiliser can be used either at planting time or when the first soil is drawn up against the young plants. To ridge or earth up the potato rows is an old-established practice. By doing this the tubers are protected from the potato blight disease, the spores of which are washed into the soil, and also to prevent the potatoes from turning green which is the result of exposure to the light. Earthing up will also control weeds growing between the rows. When the potato tops turn yellow, the crop should be lifted, laid out to dry for a few hours (not for a few days to turn green!) and then stored. Diseased or broken tubers should not be stored, and if any disease is seen, lime should be dusted between the layers of sound tubers in the store. Light must be excluded, or the tubers turn green, and frost will ruin the whole consignment. The usual practice with small quantities is to store them in sacks or boxes in a warm shed. The roots can be piled on the floor, over a layer of straw, and covered with more straw, if convenient. Where large quantities are stored, a clamp must be made. For this a flat site in the open is marked out, and beaten with the spade. Straw is laid over this and the potatoes built into a pyramid or ridge-shaped heap over the straw. More straw must cover the sides, thatchwise, and a layer, or two layers, of straw between the potatoes is also useful. To begin with, pack soil to a depth of 6 in. or more over the outside almost up to the ridge top of the clamp. After a week, more soil is placed over the whole pile, with only a few wisps of twisted straw emerging from the soil bank, to act as chimneys or ventilators and carry off some of the moisture and air. Careful building and packing of a clamp in this way allows for potatoes to be stored safely outdoors through all weathers. Potato Blight is the common cause of trouble among cultivators. To prevent its appearance spray with Bordeaux or Burgundy Mixture in June and again in July. Virus diseases have been troublesome of late years, but the best way for the amateur to combat this is to use only Scotch-grown seed. This is freer from trouble than English seed, because green fly is not so troublesome in the colder Scottish climate, and green flies are carriers of the virus—hence the recommendation to plant only Scotch seed. If home-saved tubers are grown, only use them for one season, and then plant with Scotch seed again. All potato growers should keep a watch for the Colorado Beetle, and if it is seen notify the Ministry of Agriculture at once.

**Pumpkin.**—See Marrow.

**Radish.**—In the open garden the most successful sowings are always those of spring,

when the soil has just warmed up, and showers are still frequent. Warmth and regular moisture supplies are essential, for without these the roots become woody and tough. Sow broadcast over a prepared patch of good soil, or sow in drills drawn  $\frac{1}{2}$  in. deep, and cover with fine soil. Radishes may, with great advantage, be mixed with other seeds, such as onions, before sowing. The radishes germinate very quickly—as rapidly as mustard and cress—and the roots quickly plump up if the soil is good and warmth and moisture sufficient. They are then drawn out for use, before the companion seedlings need all the space in the row. As the green leaves of the radishes emerge first, they mark the position of the seed row, and allow a hoe to be used between the rows even before the onions or other seedlings are visible.

**Rhubarb.**—This plant, used chiefly as a fruit substitute, is usually grown in the vegetable garden. Prepare the ground in autumn by deep digging and generous manuring with farm manure or garden compost. Plant in February or March, 4 ft. apart each way, with the crowns just covered with friable soil. Mulch with good manure after planting, and fork this in between the plants when growth has developed in late spring. Do not pull any stems until the following spring. Remove flower-heads if they appear, and keep the plants well supplied with moisture and liquid manure. Keep up the winter dressing of manure and spring forking every season, and if early supplies are wanted, cover one or two of the crowns with inverted boxes or tubs and a packing of loose litter. This can be done in mid-winter for early-spring supplies. Or plants can be lifted and replanted in boxes to stand under the greenhouse shelves. Lifted in autumn, stood in a warm position outdoors for a week or two, and then brought into the glasshouse, they will produce forced rhubarb for Christmas and the following month.

**Rue.**—See Herbs.

**Sage.**—A hardy shrub, easily raised from cuttings taken off in the autumn, and inserted in sandy soil in the open. Seeds can also be sown, but the quality of seedling plants is variable, and they are more prone to flower than some of the sage plants from which raisers usually take their cuttings. Sage will grow for many years, but in a small garden it is best to raise fresh plants now and then and do away with the old ones. The leaves are harvested and dried in summer, just before the plants would normally flower, and cutting off the tops for harvesting produces bushier growth.

**Salsify.**—A root, somewhat like a small parsnip, which is appreciated by epicures. It grows best in light loam, and can be treated in the same way as carrots.

**Savoy.**—See Cabbage.

**Scorzonera.**—A root rather similar to Salsify, and cultivated in exactly the same manner.

**Sea-Kale.**—A perennial plant which is a native of our shores. It can be grown from seeds sown in March or April. For this method the seeds should be sown at 6 in. intervals along drills drawn 1 in. deep and 1 ft. apart. Leave the seedlings where they stand for two seasons, and then plant out in permanent beds to produce forcing crowns. The more usual method is to buy roots or "thongs" for planting. The roots can be set out in March, 9 in. apart in groups of three, with 3 ft. from group to group. Pile a little sifted coal ash over each to keep off slugs. Clear away the tops when they die down in autumn, and cover the crowns with boxes, as in the case of rhubarb, to force the new growth and blanch it at the same time. Crowns can be covered in succession to keep up the supply. Crowns that are not covered will probably try to produce a flower-spike later, and these must be cut away, as flowers must on no account develop—in fact, treatment can be much the same as for rhubarb. Liquid manure or dressings of nitrogenous fertiliser well washed in during summer are a help to the crop. Sea-kale can also be grown and lifted to force in the greenhouse. One-year-old plants are set out in rows, with 1 ft. from set to set. In November or December these are lifted, trimmed of leaves and side shoots, and stored until they are wanted for forcing. Meanwhile the smaller thongs or

roots are cut off and pieces 6-8 in. long are cut out, with a straight cut across the top and a slanting cut at the bottom, so that they can be set out right end up when planting. Store these in sand, or bury them all together in a sheltered border until planting time in March. The trimmed roots for forcing are planted in batches, five or six at a time in a large flower-pot of fine soil, watered well, covered with a second pot inverted over them, and the hole blocked up to exclude light. These stand in the warm greenhouse under the staging, or in a similar warm position, and in two or three weeks, if they are kept warm and moist, sufficient top growth will have developed for cutting.

**Shallots.**—A popular crop for small gardens. Shallots are purchased as bulbs, like small onions. These are planted in February, or whenever there is a fine opportunity after the New Year. The bulbs are pressed a little more than half-way into soft, recently forked soil, 10 in. apart in the rows with 1 ft. between the rows. Keep the rows weeded, and in early July the crop should be ready to lift. Pull it up, and dry the bulbs off a little on trays before storing them in string bags, or in any dry place where air will circulate round them but frost will be excluded.

**Spinach.**—Two types of spinach are grown in gardens—prickly and round seeded. The round seeded is reputed to be less hardy than the other, but it will grow all the year round if sowings are made in March, May, June, and August. Sow in drills drawn 1 in. deep and 1 ft. apart. Thin out a little if the seedlings are very crowded, leaving 4 in. from plant to plant. Small plants can be drawn out to use in the salad bowl. Others should grow on, about 8 in. apart, to provide leaves for cooking. Gather a few leaves from each plant along the row, not all from one plant, and the supply will continue for a long time.

**Swede.**—See Turnips.

**Tarragon.**—Herb used to flavour vinegar. Easily raised from root division in spring or autumn. Cut down and dry for use in winter.

**Thyme.**—Perennial, but best grown fresh from seed every second season. Sow in April, and plant out the seedlings 4 in. apart in rows 10 in. apart.

**Tomato.**—Popular summer vegetables, very good in the open garden in favourable seasons, but failing to ripen well if the season is wet and sunless. Raise seeds under glass in early spring, or buy plants to set out in the garden at the end of May. Tomatoes can be grown in different ways. The most common, and probably the best for this country is to restrict each to a single vine, removing all side growths, and only allowing leaves and fruit trusses to remain on the vine. Take out the tip when four trusses have set. The vines need a bamboo cane to each, and must be frequently tied and attended to. Feeding with liquid manure through the summer is also needed. Soil should be good, rich loam, of friable texture. The chief trouble with outdoor tomatoes is the Blight disease, similar to that which attacks potatoes. To prevent this, spray the plants thoroughly in the first or second week in August, with Bordeaux Mixture. Fruits that fail to ripen outdoors can be wrapped separately and stored in an even temperature of 50° F., when they will ripen without shrivelling if they are fully grown when gathered. Small immature fruits should be used at once for pickling when the crop is harvested in September. Tomatoes are also grown extensively in glasshouses, but apart from careful regulation of ventilation and water supplies, the cultural methods are similar to those outdoors.

**Turnips.**—Rich, friable loam, not freshly manured, but in good heart, should be used for turnips. Sow short rows at any time from spring onward, but sow the main crop in July, when there is less danger of trouble from the Turnip Fly. Early sowings should be dusted with flea-beetle powder from the sowing day until the rough leaves have formed, every day or two, to control this pest, which makes holes in the seed leaves and sometimes ruins the crop. Sow in drills 1 ft. apart, and thin out to 6 in. apart. Use the turnips when they are of the size of tennis balls. Seeds can also be sown in September, left almost unthinned, and the tops used as "greens" in spring. Swedes are grown in similar manner to turnips.

## IV. GARDENING THROUGH THE YEAR

## JANUARY

**Plan for the year.** Put in hand big alterations in lay-out. Order seeds, fertilisers, insecticides, new tools, and all other requirements.

**Dig vacant ground.** Use garden compost or manure as necessary, chiefly in the vegetable garden. Fork over the top soil between herbaceous plants. Fork between rows of soft fruits.

**Protect tender plants outdoors** with light litter, cloches, or piles of sifted ash over crowns. Set boxes in position over rhubarb and sea-kale.

**Remake paths,** and repair other non-living features in the garden.

**Plant hedge shrubs** during mild spells. Also rhubarb, mint, horse-radish, and all kinds of deciduous shrubs and trees including orchard subjects, when the soil is frost free.

**Prune orchard trees,** outdoor grape vines, and soft fruits. Red, white, and black currants, gooseberries and autumn-fruiting raspberries can be pruned when the weather is not severe. Apples and pears can be pruned, and winter washes may be used after pruning. Avoid mid-winter pruning of stone fruits: silver-leaf-disease spores are active at this season. Paint over large wounds with white-lead paint or creosote. Begin to prune wall shrubs and climbers in open weather.

**Sow sweet peas,** begonias, gloxinias, freesias, aubergines, tomatoes, cucumbers, under glass in heated greenhouse. Alpine strawberries may also be sown in pots.

**Force in the greenhouse:** chicory, rhubarb, sea-kale, and asparagus.

**Start into growth dahlias** and other summer-bedding plants from which freshly rooted cuttings will be needed.

**Clear away snow** from evergreens: heavy falls may ruin their appearance.

**Make new lawns** from turf except during frost. Top dress old lawns with sifted compost, containing organic matter and fertiliser.

**Set potatoes to sprout.** Plant a few in the cold frame for an early supply.

## FEBRUARY

**Prepare a sowing and planting plan** for each border. Make ready seed-boxes, plant labels, and other requirements to put these plans into operation.

**Dig or fork over ground** in preparation for seed sowing. Dust lime over all vacant, dug land in the vegetable garden. Turn over compost heap as needed. Prepare trenches for sweet peas, runner beans, and other crops that need rich, moist soil.

**Protect outdoor crops and flowers.** Press soil back round stems if these have been raised by frost action.

**Repair paths damaged by frost.** Continue to make and repair garden features such as fences, pillars, pergolas, and steps.

**Sow seeds under glass** of leeks, tomatoes, cauliflowers, dwarf French beans, cucumbers, lettuce, and radish. Also sow seeds of half-hardy annuals such as China asters. Sow in cold greenhouse or frame mustard and cress, broccoli, cabbage, and corn salad. Sow outdoors on warm soil, when the ground is frost free: broad beans, early peas, parsnips, spinach, and turnips. Sow marrows, pumpkins, and gourds in frames over hot-beds.

**Plant Jerusalem artichokes,** shallots, chives, horse-radish, sea-kale, and if the weather is fine plant out autumn-sown onions in light, rich soil. Plant anemone tubers, ranunculus, lilies, and other summer-flowering bulbs, also delphiniums and other herbaceous plants if the weather is mild and open. Plant a few early potatoes in a warm border: prepare to protect them when the tops appear above ground. Plant deciduous shrubs and trees, including roses.

**Prick out seedlings** sown in January under glass. Set seed potatoes to sprout.

**Prune back fuchsias** and other shrubs that have rested in their pots during winter. Restart into new growth by giving warmth and moisture, and take cuttings as soon as possible. Finish orchard and fruit-garden pruning.

**Take cuttings** of chrysanthemums, carnations,

and bedding plants of all kinds under glass. Layer hardy shrubs.

**Prune hardy shrubs** of the kind that flower late in the season on shoots of current year's growth, such as *Buddleia variabilis*.

**Dress strawberry beds** with bone-meal, after cleaning and hand weeding. Fork this dressing in lightly.

**Use fertiliser** on lawns that are over heavy clay, and also on orchard fruits: it takes longer for spring and summer fertilisers to penetrate clay and reach plant roots.

## MARCH

**Order immediately** if they are not yet to hand: seeds of hardy annuals for the flower border; hardy plants for the mixed border, shrubs, and

LEVER OVER TO PRESS  
SOIL FIRM AGAINST  
BALL OF SEEDLING

**A METHOD OF PRICKING OUT SEEDLINGS.**—A pointed stick is used to make a hole. Roots should be buried to the first seed leaves and soil pressed lightly against the roots as shown.

trees: lawn seed for repairs and for new lawns. Order also quick-acting fertilisers for use in spring and summer.

**Sow outdoors,** for succession, carrots, peas, broad beans, spinach beet, lettuce, radish. Sow hardy annuals, broadcast in patches, or in lines for formal beds and edgings. Sow main-crop parsnips (if not sown in February), peas, onions, and summer spinach. Sow herbs including parsley. Sow in a nursery bed Brussels sprouts, kales, cabbages, lettuce, savoys, broccoli, and celery (if no glass available). Sow under glass, in heat, cucumbers, melons, tomatoes, and small salads. Also capsicums and aubergines.

**Plant Jerusalem artichokes,** chives, and horse-radish if these were not planted in February. Plant early potatoes, sea-kale, cabbage (including red cabbage), and mint. Plant out autumn-sown sweet peas, autumn-sown onions, strawberries, and any biennials not put out in autumn, such as Canterbury bells, sweet williams, polyanthus, and forget-me-nots. Fill gaps where plants have failed.

**Lift old leeks,** heel them in somewhere, to keep them in condition but prevent further growth.

**Make up mounds** for cucumbers (indoors and outdoors), marrows, and pumpkins.

**Prick out lettuce and tomato seedlings** when they are large enough to handle. Pot up tomatoes and gradually pot them on into larger sized pots.

**Watch for disease and pests.** Use preventive measures. Spray black currants with lime-sulphur when the leaves are the size of a florin. Spray apples with lime-sulphur against Scab. Set traps of Meta for slugs.

**Prune roses** in the last week of the month, pruning the hardy bush type first and leaving the tea roses until the first week of April. Prune climbers, but not ramblers, except where these have been damaged by gales.

**Feed spring cabbages.** An ounce of nitrate of soda per yard run of the row, hoed in, but kept

well away from the foliage, will assist the formation of good hearts.

## APRIL

*Hoe* from now on, regularly, between all developing crops. Also in the flower borders until the plants leaves completely hide the soil from view. Hoeing conserves moisture, destroys weeds, and aerates the soil so that useful micro-organisms can live in it.

*Sow* outdoors, on the main vegetable plot: onions for pickling, beetroot, turnips, dwarf beans for winter use, kohlrabi, and endive. Also for succession lettuces, radishes, peas, spinach, carrots, and broad beans. Sow more parsley. Sow in the nursery seed-bed brassica crops of all kinds, including sprouts, broccoli, and also sea-kale. Sow under glass: celery (late crop), cucumbers, and marrows for outdoor culture, outdoor tomatoes, melons for frame culture, sweet corn. On warm, rich soil, sweet corn can be sown in the open where it is to mature.

*Prick* out seeds sown in boxes, such as sprouts, cauliflowers, and celery. Pot up tomato seedlings separately and pot on as needed. Prick out into boxes, 2 in. apart, half-hardy annuals for the mixed borders and formal beds.

*Start* *salvia patens*, also *dahlias* and *cannas* if these are not already sprouting. Take off cuttings when growth is sufficiently advanced.

*Cut back* winter-flowering *jasmine*, *forsythia*, and similar shrubs that flower early on one-year-old wood, as soon as the flowers have faded.

*Plant* main-crop potatoes, globe artichokes, melons (on hot-beds), onions that were sown under glass in January, cauliflowers, and lettuce seedlings. Plant gladioli, and set out young plants of carnations, antirrhinums, pansies, sweet peas, and other hardy flowers. Plant evergreen hedges.

*Stake* early peas and sweet peas. *Prune* roses; this work should be finished in the first week of the month.

*Watch* and prepare for pests. Spray gooseberries (to prevent mildew) and black currants (to prevent Big Bud) with lime-sulphur. Spray apples and pears with lime-sulphur to prevent Scab. (Pears may need Bordeaux Mixture instead of lime-sulphur.) Make sure that supplies of derris are in hand for routine spraying in all parts of the garden should aphides appear.

## MAY

*Warning!*—Sunshine will raise daytime temperatures, sometimes to great heights. Watch frames and glasshouses, ventilate freely in the day, and shade seedlings if necessary to prevent scorching. Close ventilators an hour before sundown if there is likelihood of night frost.

*Sow* outdoors this month any half-hardy or tender crops or flowers. They will not appear through the soil until danger of night frosts is past. Sow runner beans, French beans, haricots, beetroots, marrows, pumpkins, gourds, sweet corn, in positions where they will mature. Sow tender annual flowers where they will mature; also sow biennials for next year in the open garden. Rows across the vegetable garden may be the best way to make room for these. Sow perennial flowers in a nursery bed in the open. These should be pricked out as soon as possible and left undisturbed until the first flowers have appeared. Sow for succession peas, lettuces, radishes, spinach, and turnips. It is still not too late to sow ridge cucumbers under glass. Sow flowers for greenhouse decoration, including cinerarias and primulas for late winter. Sow broccoli and endive on the nursery seed-bed.

*Plant* Brussels sprouts, broccoli, cabbage, kale, savoy, cauliflowers, leeks (if ready), lettuces, sea-kale (seedlings), and finish planting potatoes. Plant out chrysanthemums, dahlias, snapdragons, petunias, pentstemons, China asters, verbenas, and all summer bedding plants, leaving the more tender kinds until the last week of the month. Plant out beans and sweet corn raised under glass. Plant water lilies.

*Make* celery trenches if these are not yet ready for the plants. Set out lettuce seedlings on the ridges. Plant celery as the plants become available from the boxes.

*Prick* out seedlings of brassicas and other plants under glass and in the nursery beds.

*Pot up* tomatoes into large flower-pots for the cold greenhouse. Harden off plants intended for the open garden, and plant them out at the end of the month.

*Earth up* early potatoes. Straw the strawberry plantation and remove runners.

*Prune* shrubs that have finished flowering, cutting hard back those that flower on new wood. Do not cut back those that will carry ornamental berries.

*Take cuttings* of azaleas, heather, hydrangea, and other shrubs flowered under glass. Take cuttings of culinary sage, thyme, lavender, etc., and insert them in the open in shade, and keep them moist. Take cuttings of double arabis, aubretia, double sweet rockets, and other flowers which it is desired to propagate true to type. Cut back rock plants of spreading habit when the flowers fade. Layer fuchsias.

*Use* calomel dust on onion rows, naphthalene on carrots.

*Feed* green crops with nitrate of soda or sulphate of ammonia. This is also useful for onions and leeks. Attend to summer pruning on peaches, nectarines, grapes, and other trained plants.

*Bedding.* Lift spring bulbs that have flowered, heel them into good soil in a corner of the garden until the leaves turn yellow. Replace them by summer bedding plants, which can be purchased from nurseries if sufficient have not been raised at home.

## JUNE

*Keep the hoe* going among flowers and vegetables and between rows of bush fruits. Watch for pests: spray with derris where pests are attacking edible crops. Use nicotine on roses and other ornamental plants.

*Sow* Broccoli and endive in the seed-bed, and swedes, beet, lettuce, carrots, dwarf peas, radish, spinach, turnips, cardoons, chicory, and mustard and cress for succession. Sow biennials if these were not sown in May. Thin out wallflowers, etc., to 3 in. apart as soon as possible. Sow home-saved seed from early-flowering rock plants. Sow under glass: anemones, primulas, cinerarias, cyclamen, herbaceous calceolarias.

*Plant* out the last of the bedding plants, such as eucalyptus and cannas. Plant tomatoes, celery, ridge cucumbers, vegetable marrows, and pumpkins. Train melons in frames; also cucumbers. Plant hanging baskets and window-boxes for the summer.

*Stake* tall dahlias, chrysanthemums, delphiniums, runner beans, tall peas, and other subjects as needed. Push in twigs among frail annuals to support them.

*Pinch* out side growths from tomatoes, tops of broad beans, side stems and tendrils from sweet peas, etc.

*Mulch* raspberries and other similar berries to encourage strong new canes for next season.

*Trim* hedges regularly. Put small clippings on the compost heap, and woody prunings on the bonfire.

*Lift* early potatoes as wanted for use. Earth up late crop, and spray with Burgundy or Bordeaux Mixture to prevent Blight.

*Peg* down strawberry runners that are wanted for new plantations. Remove all others.

*Shade* the greenhouse if necessary. Cucumber houses must be shaded.

*Feed* crops and flowers (after the first flowers form) with weak liquid manure, applied after rain has fallen or after watering.

*D.D.T.* is useful as a deterrent to caterpillars. Derris is also useful as a summer insecticide. Spray to prevent rather than to cure!

## JULY

*Successional sowing* in the vegetable garden is still practicable, but quick-maturing types should be chosen for these late crops. Sow early dwarf peas in the first week of the month in warm, sheltered gardens. Sow carrots of short-rooted type to mature in autumn and be used as they are pulled. Sow round beet, lettuce, turnips, radish (if this can be supplied with water), mustard, and cress. Sow prickly seeded spinach. Under glass sow carnations, primulas, cyclamen, herbaceous calceolarias, and any kind of annual to flower in late autumn. Dwarf French beans can be sown

in large pots in the greenhouse to mature after the first frosts.

*Plant colchicums.* Plant out seedlings of annuals that are too crowded. Plant broccoli, cabbages, cauliflowers, celery, kale, leeks, and endive.

*Prune* all wall-trained trees, grape vines, etc., as needed. Thin out fruits and attend to supports. Prune bush roses by cutting blooms with very long stems. Remove stems that crowd on small bush fruits. Cut back some of the side growths on red and white currants and gooseberries, to prevent overcrowding and to encourage spur formation. Treat apples in the same way. Continue to prune shrubs after they have flowered, according to their needs.

*Thin out* seedlings of beet, parsley, carrots, swedes.

*Earth up* celery. Watch for leaf spot or leaf miners.

particularly daffodils, scillas, and muscari. When ordering bulbs, calculate roughly what other plants are available, such as wallflowers and polyanthus. These help to keep down the bulb bill.

*Sow* in the vegetable garden, turnips for turnip tops, winter spinach, spinach beet, lettuce, radish, and corn salad. Sow mustard and cress for succession. In the first week of the month sow cabbages for spring. Sow winter-flowering and Brompton stocks, and schizanthus to bloom on the greenhouse shelves, with other annuals such as browallia, felicia, mignonette, etc., as desired. Sow rock plants such as Edelweiss in the alpine house. Sow antirrhinums, pansies, violas, Iceland poppies, and intermediate stocks in cold frames, to winter under glass.

*Plant* bulbs that have been stored during summer. Narcissus of all kinds prefer August planting. Other spring bulbs, except tulips, can be planted as the beds become vacant. Plant out

**METHOD OF ROOT PRUNING** too-vigorous fruit trees. The operation is done in two stages. The second may be omitted if the tree becomes fruitful.

*Train* tomatoes, roses, chrysanthemums, blackberries, and loganberries.

*Take cuttings* of roses, carnations, pinks, and any other subjects in the flower garden on which there are suitable pieces for propagation. Layer carnations, strawberries, blackberries, and allied berries.

*Spray* with liver of sulphur or dust with sulphur powder to control mildew under glass and in the open. Spray with Bordeaux Mixture or Burgundy Mixture to control Blight on potatoes. Paint patches of American Blight on fruit trees with methylated spirit or paraffin. Spray roses with colloidal sulphur against Black Spot.

*Feed* chrysanthemums, tomatoes, dahlias, and other actively growing plants with liquid fertiliser. *Bud* fruits, ornamental trees, roses, and similar subjects if stocks are available.

*Cut out* diseased or broken plum branches: burn at once.

*Harvest* shallots. Lay them out to dry well before storing. Gather rose petals for pot pourri. Gather herbs for drying.

*In northern gardens* sow cabbage in the last week of the month.

## AUGUST

*Bulb catalogues* arrive this month. Order and plant at once those bulbs intended for exhibition,

rooted cuttings, biennials, and divided roots of spring-flowering subjects, where they are to flower. Plant cabbages, broccoli, late celery, and leeks if these still remain in the seed-bed. Plant strawberry runners in new plantations.

*Pot up* under glass amaryllis, cyclamen, freesias, Roman hyacinths. *Pot* on seedlings of cinerarias, primulas, and other greenhouse subjects. Plant bulbs in bowls of fibre.

*Prune* shrubby climbers if they are growing too large. Trim lavender hedges after the flowers are harvested. Finish summer pruning of fruits. Cut out old canes from raspberries and loganberries. Remove unwanted stems on vines. Thin out the bunches of fruit with grape scissors.

*Take cuttings* of rock plants, bedding plants, and bush roses.

*Lift* potatoes as required. Bend down tops of onions: lift and ripen a week or two later, and harvest when ripe and dry.

*Burn* old potato haulms. Burn the straw between the rows of strawberries: this will clear the plot and prevent disease.

*Spray* tomatoes outdoors with Bordeaux Mixture in the first or second week of the month, to prevent the appearance of Blight.

*Remove* dead leaves from melons. Allow all the sunshine possible to reach the fruits.

## SEPTEMBER

*Lawns* can be made or renovated this month. Allow 1-2 oz. of seed per sq. yd. for an ordinary pleasure lawn, and sow grass of a strong-growing, medium quality.

Sow in the open garden antirrhinums, sweet peas, and other annuals, sheltered positions must be found for these sowings. Sow radish and lettuce for succession, and corn salad for use in winter. To provide early heads of cauliflower, sow in a frame or greenhouse and grow them on under glass. Sow spinach and turnips (for tops), also onions if these were not sown in August.

Sow French beans to grow in large pots in the warm greenhouse and also tomatoes for early spring, in a heated house.

Plant all spring-flowering bulbs except tulips. Remake herbaceous borders if the contents are mainly early-flowering subjects: lift and divide such roots as delphiniums and plant out fresh varieties. Plant new rock plants, including dwarf bulbs which can be interplanted with mossy saxifrages or other carpeting plants in the same

be attacked by soil pests. Lift gladioli corms: hang them in bunches to dry, clean and sort them over before storing. Remember to store all roots in a frost-proof place, and to use slightly damp sand if there is any danger of shrivelling.

Protect late crops such as lettuces with cloches if these are available.

Thin out autumn sowings, but not too much: winter may do some thinning for you.

Sow in heated glasshouses mustard and cress and radishes for succession. Sow broad beans in the open, if the garden is sheltered and the soil light and warm.

Plant all kinds of hardy herbaceous plants in the flower garden and rock-garden. Plant bulbs and spring bedding plants including the plants raised in the nursery, such as wallflowers. Plant deciduous trees and shrubs of all kinds, including orchard fruits. Cabbages, lettuce, and endive can still be set out if desired.

Pot up arum lilies, lilies of the valley, spring bulbs, summer bedding plants that have not finished flowering, and any available annuals that were sown late and are near to flowering stage.

ROOTS WELL SPREAD OUT

**HOW TO PLANT A FRUIT TREE.**—A hole wider than the extent of the roots' spread is made, then a stake is placed in position and the tree tied temporarily while planting is done. Soil is worked between the roots and well trodden. A piece of sacking is placed round the tree to prevent chocking and cutting by the tie.

TREAD FINE SOIL OVER ROOTS

rockery pocket. Plant evergreens of all kinds, hedges and lawn specimens as well as shrub borders. Plant out rooted cuttings of all kinds that are ready to move from the propagating beds. Make new strawberry plantations. Plant cabbage, endive, kohlrabi, lettuce, savoys, and winter greens if these are still in the nursery bed. Plant violets in frames, near the glass, for winter blooming. Pot up tender bedding subjects and bring them into the greenhouse.

Prune climbers, overgrown rockery plants, and fruits as required. Root pruning may also be done now if needed. Cut out old canes from all the berry-bearing plants—logans, blackberries, raspberries, etc., if this has not been done previously. Do not tie raspberry canes to supports until the end of the winter.

Take cuttings of small bush fruits, gooseberries, etc.; rock plants; roses; hardy deciduous shrubs; bedding plants. Layer sumachs, or remove suckers to form new plants.

Bring under glass late-flowering chrysanthemums and other pot plants that have been standing in the open during summer.

## OCTOBER

Harvest crops, and make preparations for storing. Do not let root crops remain too long in the ground; they may become coarse, or may

Rhubarb, parsley, and mint can be planted into boxes, or into the soil of greenhouse or frame, to provide mid-winter supplies. Chicory can be lifted and forced.

Take cuttings of all hardy deciduous shrubs, including hedging plants, ornamental shrubs, roses, and fruits.

Prune figs, removing all fruits larger than pea-size.

Renovate grass that is worn bare in patches. Repair broken grass edges.

Disbud chrysanthemums under glass. Stake these, and also other winter-flowering subjects such as carnations.

Collect material for winter protection: mats, leaves, bracken, straw, hurdles, and so on.

Keep the garden clear of falling leaves: these encourage pests and should be gathered up and stored dry, or put into the compost heap.

Watch stored fruits and other food crops. Remove any diseased specimens from time to time to prevent infection of the whole store.

## NOVEMBER

Clear runner beans, tomato plants, marrow plants, and all such material from the vegetable garden. Stack cabbage stalks in a heap, to encourage pests to hibernate there, and after three weeks consign the heap to the bonfire.

Clear away dead leaves from rhubarb: cover the crowns with boxes and add light litter or straw manure to exclude light and frost. Crowns not to be forced should be covered very lightly with dry litter only.

Sow in very sheltered gardens, on a warm border, a row of early dwarf peas such as Little Marvel, and a row of broad beans. In exposed gardens this sowing is too risky to be worth while. French beans can be sown in heat. Mustard and cress can be sown in cool houses.

Earth up celery.

Lift sea-kale for forcing: cut thongs from the roots to replant in February. Lift Jerusalem artichokes and parsnips: lifting becomes difficult when the ground is sealed by frost, as it may be after the New Year.

Prune deciduous hedges such as the common thorn hedge. Prune fruits generally, and prepare to spray them after pruning, with some kind of winter wash, according to particular needs.

Plant roses, fruit trees, deciduous shrubs, and hedges. Herbaceous plants can be planted as long as the weather remains open and mild, and seedlings can be moved from the nursery plot. When hard frosts arrive, put an end to planting until the first mild spell of the New Year. Tulips of late-flowering types are best planted in the middle weeks of November.

## DECEMBER

During frost wheel manure to parts of the garden where it will be dug in later. Repair seed-boxes, clean pots and other materials in the potting-shed, sort over labels, stakes, tying material, and so on. Clean tools and rub them with an oily rag. Sharpen cutting tools. Paint wooden structures, tool handles, etc., and generally make ready for a new season's work.

Plant, Prune, and Spray fruit trees when the weather allows.

Earth up the latest celery.

Force rhubarb, chicory, and sea-kale.

Keep an eye on stored crops, particularly those in clamps: see that frost does not enter.

Watch plants in rock-garden and border and also watch newly planted fruits: if frost lifts them or loosens the soil round the stems, put this right at once.

Sweep and roll lawns occasionally. They may need to be cut if there are long mild spells.

Plan for next season. Make a note of this past year's failures and successes. Plan to avoid the need for buying vegetables and fruits. Plan to improve the colours and lines of the flower garden.

Construct new garden features. Order new sundries, including tools, ornaments, insecticides, fertilisers, and any non-living material wanted for improvements.

## V. MODERN GARDEN CHEMISTRY

Garden chemistry has progressed very far from the old rule-of-thumb methods in vogue during last century, and many volumes have been written on soils, insecticides, fungicides, and other matters in which research of a technical nature has been carried out to help the plant grower. It is, however, true to say that the average small-garden owner has neither the time nor the inclination to study these volumes in detail, and in fact, becomes more bewildered than he was before if he tries to "read up" such matters. The following brief notes are therefore designed to help the amateur gardener in the choice and use of some of the more important materials that are commercially offered, rather than to describe in detail the chemical origin of these mixtures.

For convenience the materials dealt with will be grouped according to their use in the garden.

(a) **Fertilisers or Materials that Enrich the Soil.**—These again may be roughly grouped into three classes—first, the important plant foods, potash, phosphates, and nitrates, together with other (important but usually present in sufficient quantities) nutrients such as magnesium and boron. Next lime, which for most plants is essential for healthy growth, though some plants like soil that is slightly acid and for these lime must be avoided. (These plants are commonly known as calcifuges, or lime-haters.) Thirdly *humus*, that is, decaying animal or vegetable matter. This last provides the essential bacteria or micro-organisms without which the soil would be dead, inert matter and would not support any kind of vegetation. Humus is added to the soil in the form of garden compost, farm or stable manure, poultry droppings, leaves, hop manure, and any similar matter.

**Lime** is available in shops in the form of "garden lime" or "hydrated lime." Another form of lime is chalk. Hydrated lime is best to use on clay soils, and chalk is good on light, sandy soils because it helps to bind them. The function of lime in the soil is twofold. Plants need some lime as food. But still more important, acid soils, that is soils without lime, tend to lock up other plant foods. Lime unlocks them by making them soluble and available to the plant roots, for plants can only absorb food in liquid form. A normal dressing of lime for a vegetable garden is  $\frac{1}{2}$  lb. of lime or 1 lb. of chalk to each square yard once in three years. Whether this is applied in three separate dressings or all at once is not very important in the small garden, and the gardener can do whatever is convenient to himself. Quick-lime can be used in place of hydrated lime, with some advantage on ground that is subject to Club Root, a disease that distorts the roots of cabbages and other brassicas. It should be laid on the plot in heaps, and in a few days it will crumble to powder, when it can be distributed over the surface in the same way as hydrated lime. Both these forms of lime should be used some weeks before other fertilisers are applied, and all forms of lime should be applied as surface dressings after digging.

**Nitrates** are soluble foods that encourage leaf and stem formation. They are used to stimulate growth among vegetables, and applied on the

"little and often" principle because of their solubility. If given in large doses, they waste by washing through the top soil before they are absorbed by the plant roots. Too much nitrogenous fertiliser should not be given late in the season to food crops that are to stand outdoors through the winter, as it will encourage sappy growth that is easily damaged by frost. Neither must too much nitrogen be given to flowering plants in the early stages, otherwise they spend too much time making leaf and stem growth, and delay flowering, which may mean that the frosts arrive before the flowers have all opened. The rough rule in the flower garden is to feed well directly the flower-buds can be seen. Fertilisers that supply nitrates are *Nitrate of Soda*, *Sulphate of Ammonia*, *Nitro-chalk* (which also contains lime), *Dried Blood*, and also any complete, balanced fertilisers of the "Growmore" type, which supply all three of the main plant foods. Of these concentrated nitrogenous fertilisers, 1 oz. in a gallon of water, applied to a square yard, is a good dressing for summer use, and can be repeated two or three times if necessary, at intervals of two or three weeks. It should always be applied after rain or after ordinary watering, and the fertiliser should go on the soil, not on the plant foliage.

**Phosphates** are foods that do two things in particular. They assist root formation, and so are very useful in seed-beds. They also encourage flower production and fruit formation, that is, they make for early maturity. Obviously they have special uses in the fruit patch, where the gardener needs to watch his trees and use fertilisers according to their requirements. If too much leaf and stem growth is present, phosphates will be used; if flowers are plentiful, but the tree makes no growth, nitrates are needed. (If the tree is growing well, flowering well, and yet failing to fruit, look into the question of pollination.) Fertilisers that supply phosphates are *superphosphate of lime*, which is quick acting and must be used in spring or summer at 1-2 oz. per sq. yd.; *basic slag*, which can be applied in autumn or winter at twice the rate, as it is slow acting; and *bone-meal* which can be used at any time when digging is done, in small or large quantity, up to  $\frac{1}{2}$  lb. per sq. yd. Basic slag contains some lime, and bone-meal contains some nitrogen. Basic

slag is only suitable for soil which contains a fair proportion of humus.

**Potash**, the third of the important foods, is responsible for the quality of the plant, for colour in flowers, for ripeness in fruits, for good general health. Some plants need much more than others. Apples of the dessert varieties need plenty; cooking kinds are less susceptible to its presence or absence in the soil. Plums generally need very little, but Purple Pershore plums become misshapen and unhealthy generally if potash is not provided. Root crops need potash, and it is best for potash to be supplied in winter, so that it gets down to the sub-soil. Moreover, most of the forms in which potash is sold—*muriate of potash* for instance—have certain impurities present which are best washed out by rains before the period of active growth. Rather less than 1 oz. of *sulphate of potash* or *potash*

**LIQUID MANURE** is made by using an old sack filled with rotted animal manure and soot in equal proportions. This is then suspended in a barrel of rain-water. After a week the liquid manure can be used diluted to the colour of weak tea.

**salts** per sq. yd. make a normal dressing for a vegetable plot. Wood ash from the bonfire contains a quantity of highly soluble potash, and if this is stored dry and used at any convenient time round flowers, vegetables, or fruits, it will reduce the need for purchased supplies. If potash is needed during the growing season and wood ash is not available, use sulphate of potash, which is the purest commercial form of garden potash.

**Other plant foods** such as magnesium and boron are normally present in most soils, and the small gardener need not concern himself with them. Soil deficiencies show up in brown edges, yellow patches, etc., on the foliage, and if troubles of this kind occur in the home orchard, an expert should be consulted. It may be noted, however, that the majority of a plant's needs will be satisfied by the use of good farm or stable manure, and a dressing of this will often put fresh life into an old garden.

**(b) Insecticides and Fungicides.**—Insecticides may act in different ways. Some are *contact sprays*, that is, they destroy insects immediately they come in contact with them. These are obviously used when the pest is at work, and are usually only effective against pests with comparatively soft skins, such as green and black flies, Derris, pyrethrum, and ordinary soap mixtures will control flies of this kind. Also on the market are several dusting powders which act in the same way, and powder distributors are sold to make their use easy and effective.

Some pests are not affected by this type of insecticide, but must be destroyed by poison as they eat. For these, which include most caterpillars, a nicotine spray, one made of D.D.T. or

lead arsenate, is most effective. As these poison sprays cannot be used on crops that are to be eaten, derris and pyrethrum are used instead, and are equally effective if they are renewed after heavy rain. The ordinary general-purpose insecticide sold today is usually a control for both surface caterpillars and green flies, and the only thing for the novice to note is that sprays should always be mixed exactly according to makers' instructions and that they should be applied with force, through a fine nozzle, in the evenings, and not while sun is scorching the plants. Care should be taken to wet thoroughly both sides of every leaf and stem, for the full effect of the spray to be felt, and in some cases a second application a few days later is needed, as some of the pests may hatch out after the first spray is given.

**Winter washes** are sprays designed to kill hibernating pests and the eggs which are laid in crevices in the bark; they also clear lichens and scale insects. To wait to spray when the pest is seen is to ask for trouble, since the first sign is possibly that the young growth, or blossom bud, is eaten through, and irreparable damage has then been done. Winter washes include *tar oil*, which is effective against the ordinary types of aphids, scale insects, apple sucker, and winter moth. *Petroleum oil* washes can be used when the buds are ready to burst in late winter, to control Red Spider and capsid bugs. *Tar-petroleum* sprays are a mixture which will serve the double purpose, but they are only in general use on black currants and other small fruits.

Sprays known as **D.N.C.** washes contain a quantity of Di-nitro-ortho-cresol. These can be used in place of both tar oil and petroleum sprays, but need greater care in application. There are also *Thiocyanate* washes which again are double-purpose sprays, and can be used even later than the D.N.C. spray.

**Soil pests** need rather different treatment. These are usually controlled by fumes—either by fumes designed to discourage the adult pest, often a flying pest, from laying eggs in or on the soil, or by fumes that rise through the soil and destroy the young grubs that are feeding in it. In the first group are *calomel dust*, which is used along onion rows to ward off the onion fly, and *naphthalene* which is used in similar manner to keep the carrot fly from the rows. *Soot and lime mixed* give off strong fumes, and also come into the group. These are used for the same purposes as calomel and naphthalene, and also to dust along celery rows and elsewhere to discourage the fly that lays eggs in the leaves. Celery flies, and other leaf miners that attack various plants, leave their eggs buried in the tissue of the leaf: the resulting maggots tunnel between the leaf surfaces and cause disfiguring marks, and lowered vitality in the plants. As the pests tunnel inside, the use of sprays is almost without result, unless the sprays are strong smelling and used, like the soot, to discourage the flies before the eggs are laid. Fumes that rise through the soil are given off by *Soil Fumigants*, chemicals often with naphthalene in their make-up, which must, of course, be buried under the top spit of soil during digging, to become effective. A mixture of crushed *Meta* tablets with some kind of bait is a good *slug killer*.

The horticultural chemists have experimented with all these various kinds of insecticides, and have produced easy-to-use commercial preparations which are usually a wise purchase. In the small garden it does not often pay to buy large quantities of a single chemical, but is better to buy prepared mixtures which are frequently suitable for the control of several kinds of pests. It is, however, very important that the makers' instructions should be accurately followed, and (although this should not need mentioning) it is important also to see that the makers do recommend the insecticide in question for the purpose for which it is being used.

**Fungicides** are possibly more misunderstood by gardeners than are insecticides. Fungus diseases may be present only inside the tissues of the plant, or may be on the surface only at certain seasons. *Lime-sulphur* is one of the most common fungicides, and it also acts as an insecticide against Red Spider and the Big Bud mite of black currants. Not all plants can be sprayed with sulphur preparations during active growth, and fungicides must always be used with great caution. *Bordeaux*

*Mixture* is one of the most valuable, and generally safe, fungicides, and in a small garden this, with perhaps a little green sulphur powder (for use against mildew) may be all the fungicides that are necessary. *Burgundy Mixture* is somewhat similar in action, easy to mix, and good for potatoes, but not generally suitable in the fruit garden.

*Horticultural D.D.T.* and *Gammexane* are among the newer insecticides, and both promise good results. *D.D.T.* is effective against such widely differing pests as flea beetles, rose chafers, asparagus beetles, raspberry beetles, Colorado beetle, pea aphids, codling moth, cabbage looper, and onion thrips, but no use against green flies. On the other hand, it is also fatal to lady-birds, which as every gardener knows, are his friends, and work with him to keep down green flies. Both *D.D.T.* and *Gammexane* form a part of many commercial insecticides, and until much more can be said with certainty about their action, the gardener must rely on the horticultural chemist to add them when and where they will be effective as insecticides but harmless to plants. Marketed preparations are, almost without exception, safe to use according to instructions, and the owner of a small garden will do well to buy them.

Yet another insecticide is *H.E.T.P.*, a substance which is still in the experimental stage. It is not likely to outshine *D.D.T.* for general purposes, but it has already been found to be the best-known substance for control of aphides, and more may be heard about it in the future.

(c) *Weed-killers*.—Arsenical weed killers are rather out of favour with the modern gardener. They are dangerous to handle and still more dangerous to store. If they are stored, it should be only under lock and key.

*Weed-killers* in modern use are of two types—those that kill all vegetation, such as the ones used on gravel paths, and those that are selective in action, such as the weed-killers used on lawns. *Weed-killers* for gravel paths are sold in prepared form, but none are more useful than *Sodium chlorate*. This, mixed with water at the rate of 2 oz. in a 2-gallon water-can, and sprinkled over the path surface, will destroy all the weeds. The effect is not seen for some days, but the plants ultimately die out. Unless some kind of waterproof surface is laid down, more weeds will, of course, develop after a time, and these will need to be treated with more sodium chlorate.

*Sulphate of ammonia*, which is also a stimulant to growth, acts as a weed-killer on lawns, its action being due to the fact that the chemical stays where it falls on the broad horizontal leaves of daisies and plantains, while it falls off the vertical grass blades, and gets carried down by dew or rain to the roots, to feed them. Thus the leaves of weeds are burned, while the grass is not burned to any appreciable extent but is stimulated to stronger growth. Frequent small doses of sulphate ( $\frac{1}{2}$  oz., mixed with sand, applied to each sq. yd.) are better than a single heavy application.

There are also selective weed-killers that destroy every plantain and have almost no ill effect on grass. These are excellent for use on well-established grass lawns where weeds are very plentiful, and as they have merely to be watered down, and then watered on, application is simple. They destroy through the digestive system of the plant, and are fully effective on several kinds of weeds. On others the treatment may have to be repeated, but a selective weed-killer—of which there are several on the market—is a good investment for an old lawn. If a very young lawn from seed becomes weedy, it would probably be wiser to wait until the end of the first season or beginning of the second season before applying the weed-killer, to avoid any possible damage to very young grass.

(d) *Root-forming or Growth-promoting Substances*.—Of recent years much has been heard about root-forming substances which can be used to accelerate root growth when cuttings are inserted. This is marketed under names such as *Hortomone* and *Seradix*. The chemical which forms the base of this substance is the one that is present in all plants, and which responds to stimulus when plants are stood in a sunny window. Everyone has noticed that such plants become "drawn" towards the sun, or to put it more accurately, the part of the stem that is in the

shade grows more rapidly than the part in full sunshine. The growth-forming substances have been found in the part of the plant that was growing most rapidly. The horticultural chemist has been able to isolate this substance, and to produce it in quantity for the use of the gardener. Properly used, *Hortomone* and *Seradix* preparations will do what is claimed for them by their makers.

### GARDEN CHEMISTRY CALENDAR

**January**.—Spray fruit trees with tar-oil winter wash against aphids and apple sucker.

Use soil fumigants as needed when digging newly broken grassland or ground known to be infested with soil pests. (N.B.—*D.D.T.* is used effectively against wireworms in some modern soil fumigants).

**February**.—Dress lime over freshly dug ground: wait for a few weeks before using any fertilisers. Dress lawns on heavy soil with sulphate of ammonia when the weather is mild and open. Spray peaches with colloidal copper against Leaf Curl.

**March**.—Spray with *D.N.C.* to control Red Spider, Capsid Bug, and caterpillars (instead of previous tar oil, not in addition). Spray pears with *Bordeaux Mixture* against Scab.

Use superphosphate of lime, or sulphate of ammonia as soil dressings according to needs of fruit trees and vegetables. Use bone-meal in renovation of flower borders. Dress lawns with sulphate of ammonia if selective weed-killer is to be used later.

**April**.—Spray pears and apples (except sulphurshy varieties) with lime-sulphur in pink-bud stage, against Scab.

Dress spring cabbages with nitrate of soda. Use sulphate of potash and superphosphate when planting potatoes.

**May**.—Dust onion rows with calomel dust against onion fly.

Dust naphthalene along carrot rows to ward off carrot fly.

Spray with lime-sulphur, at petal-fall, apples, plums, and damsons. If desired, add nicotine to the spray to control sawfly and aphids.

Spray gooseberries with washing soda ( $\frac{1}{2}$  lb to 2½ gallons water), with soap added as spreader. Dust raspberries and other berries with derris dust to control beetle. Spray raspberry canes with colloidal sulphur if necessary against Cane spot.

**June**.—Use nitrate of soda or sulphate of ammonia where quick-acting stimulants to growth are needed.

Dust carrots and onions, as last month. Spray broad beans with derris insecticide. Dust newly planted brassica seedlings with calomel or naphthalene to control cabbage-root fly. Use derris dust or spray on raspberries and loganberries. Spray pears with *Bordeaux Mixture* against Scab.

**July**.—Spray main-crop potatoes with *Bordeaux* or *Burgundy Mixture* to prevent Blight. Spray celery also to prevent Leaf Spot. Feed celery with nitrate of soda or sulphate of ammonia, and chrysanthemums with liquid manure.

**August**.—Spray celery with *Bordeaux Mixture* and dust foliage with soot.

Spray tomatoes in the first or second week, with *Bordeaux Mixture*.

Use *Hortomone* or *Seradix* on cuttings taken this month.

**September**.—Dust and spray celery as last month. Feed with a complete balanced fertiliser crops that are to stand the winter.

Dress strawberry beds with basic slag as they are made ready for new plants.

**October**.—Use basic slag in the fruit garden as needed.

Dress ground with lime after digging. Use a dusting of lime among potatoes going into store.

**November**.—Use lime, sulphate of potash or muriate of potash, and bonfire ash, as needed during digging, and in the orchard.

**December**.—Use tar-oil winter wash from the middle of the month onward, after trees have been pruned.

# Radio, Television and Radar

# Radio, Television and Radar

By T. W. BENNINGTON AND M. G. FOSTER, A.M.I.E.E.  
(Engineering Division, B.B.C.)

## RADIO.

**Historical.**—Though it is not possible to ascribe the "invention" of radio to any one man, it is true to say that its discovery and subsequent development as a means of communication was primarily due to the work of three. Between them—not, of course, together—these three conceived the idea of wave motion through space, of its use as a means of communication, explained and proved the physical processes involved, and brought the idea to practical fruition.

The theory of electromagnetic waves—of which the radio wave is one—was originated by the British physicist James Clerk-Maxwell in 1864. He formulated a set of equations which have become famous as the basis of the behaviour of electromagnetic waves in space. These showed that both electrical and optical phenomena in space are essentially similar in character, and that the waves if short in wavelength are those of light, whilst if of longer wavelength they are radio waves. Clerk-Maxwell was never, in his own lifetime, to see such waves actually produced by electrical means, yet by his purely mathematical investigations he laid the foundation upon which the art of radio communication was to be built.

When Heinrich Hertz—the second member of the trio—succeeded in 1888 in producing such waves by electrical means he found them to conform to Clerk-Maxwell's theories in every particular. Although Hertz's work was purely in the nature of laboratory experiments, he made many useful discoveries about the waves themselves, and about their behaviour under differing conditions, and also about the apparatus necessary for producing them.

It fell to Marconi to develop the use of radio waves as a practical means of communication. He came to England in 1896 after carrying out his early experiments in his native Italy, and a British patent for his apparatus was at once granted. Encouraged by the sympathetic interest of the British Post Office, Marconi soon succeeded in establishing communication between Penarth and Weston-super-Mare. Following this achievement, he rapidly effected improvements in the apparatus, which increased its range. In 1897 the first Wireless Signalling Company was formed, and in 1898 the first two paid wireless messages were sent, in this country. By 1900 Marconi had amply demonstrated that communication by radio was a commercial proposition, and radio stations for regular operation on ship and shore were being built.

In 1901 Marconi went to America, there to attempt the reception of radio signals sent out by his station at Poldhu in Cornwall. And on 12th December, 1901—after innumerable difficulties had been encountered and overcome—the famous "S" signals of the Morse code sent out from Poldhu were received in Newfoundland, thus proving that radio waves could pass from the Old World to the New, and—most important discovery of all—could bend around the spherically shaped earth.

It was not easy to explain this point at first, for it was part of the theory that radio waves—like those of light—must, so long as they travelled constantly in a medium like air, move in straight lines. Some slight "bending" or diffraction over the horizon was understandable, but this was insufficient to account for the waves reaching Newfoundland. Then, almost simultaneously, the British physicist Oliver Heaviside and the American Dr. A. E. Kennelly came forward with an explanation. They suggested that the air in the upper atmosphere had different electrical properties from that lower down. It was not, like the

latter, an electrical insulator, but a conductor, and as such had the property of "refracting" the waves, and so of causing them to curve round in the upper atmosphere so that they returned to earth at a far distant point, thus enabling them to travel round the spherically shaped earth. The Kennelly-Heaviside "layer" theory was soon accepted by the world of science because it explained known facts about the behaviour of radio waves, though it was not until 1925 that the British scientist Sir Edward Appleton first determined the actual position of the layer in the atmosphere.

In the meantime the art of radio communication had progressed by leaps and bounds. Many scientists and inventors, both in this country and abroad, had contributed to this rapid advance, but perhaps the most far-reaching contribution of all was the invention of the radio valve by Sir Ambrose Fleming in 1904. This—one of the most remarkable of all of man's inventions—was destined not only to revolutionise radio telegraphy but also to solve the problems which had so far prevented the successful development of radio-telephony, and eventually to make possible the transmission of high-quality speech, music, and even vision signals, and thus lead to broadcasting and television.

Although one of its most useful applications has always been as a means of communicating with ships at sea, radio has spread to so many other fields that to-day the whole world is closely linked by a vast and complicated network of radio communications. The broadcasting of news and entertainment—which began in this country in 1920—is now an almost essential part of normal civilised life, the transmission of still pictures and of living scenes is rapidly becoming so, whilst radar has brought about startling changes in marine and aerial navigation. In little more than half a lifetime the experimental toy of a young inventor has developed into a practically indispensable amenity of everyday life.

A complete understanding of radio can be acquired only by long study of the electrical and scientific facts and principles involved, but in the notes which follow we shall endeavour to give an insight into some aspects of radio communication and into the general working of some of the apparatus in as simple and non-technical a way as is possible.

**Radio Waves and How They Travel.**—When an electric charge is oscillating along a radio transmitting aerial it produces both an electric strain and a magnetic strain in the surrounding space and these two forces act at right angles to each other. At the conclusion of each oscillation the two strains are "broken off" and lose their contact with the aerial. The resultant disturbance in space constitutes an electromagnetic or radio wave. These waves do not require any material medium to support them—they can exist equally well in a vacuum. Thus we may discard the old conception of an "Aether" in which radio waves were once thought to travel. The waves travel through space with a velocity of 186,000 miles or 300 million metres per second. They travel through ordinary air at the same rate, but if they enter a medium with different electrical properties from those of air their velocity is altered.

We have seen that one complete wave leaves the aerial for each complete oscillation of the electric charge, and thus it is obvious that their rate of emission depends on the "frequency" of the electric oscillations being generated by the radio transmitter. If the charge be oscillating up and down the aerial 300 million times per second the frequency will be 300 million "cycles" per second.

At the end of one second the front of the first wave will be 300 million metres away from the aerial—since the waves travel that distance in that time—whilst the last wave will just be leaving it. Three hundred million waves will, therefore, occupy the distance between the first wave front and the aerial, and thus the distance occupied by each wave, i.e., the “wavelength,” will be 1 metre. If the charge is now made to oscillate 100 times more slowly than before—at a frequency of 3 million cycles per second—then at the end of one second there will only be 3 million waves occupying the 300 million metres of space. The wavelength will therefore be 100 metres. Thus a wave of low frequency has a long wavelength, whilst a high-frequency wave has a short wavelength. To obtain the relation between the two quantities it is only necessary to remember that Wavelength (in metres) equals Velocity (in metres per second) divided by Frequency (in cycles per second). Radio waves range in length from about 30,000 metres at the long-wave end to less than a centimetre in the case of the shortest waves.

and about 300 miles above the earth's surface. In this region the air is not an electrical insulator but a partial conductor—a property imparted to it by the action of the sun.

On entering the ionosphere the velocity of the wave is changed and, instead of continuing in a straight line, it is gradually turned round and eventually directed downwards again towards the earth. Successive reflections of the wave between the ionosphere and the earth enable it to travel great distances in a series of “hops,” as indicated in Fig. 1.

Now the action of the ionosphere upon the waves varies, not only with the time of day and season, but also with wavelength. Medium waves are not reflected—at least not during the day—but are lost within the ionosphere, hence their range depends on that of the ground wave. At night however, some reflection does take place, and that is why—for example—distant medium-wave broadcasting stations may sometimes be heard at night and not during daylight. It is their “sky” wave and not their normal ground wave which

TABLE I

Class.	Wavelength Range, Metres.	Main Characteristics.	Principal Uses.
Long Waves.	Above 1,000	Travel long distances over earth's surface, also to greater distances by reflection from ionosphere.	Navigational aids, medium and long-distance point-to-point communication “National” broadcasting.
Medium Waves.	1,000 to 100	Travel over earth's surface only during the day, some reflection from ionosphere at night. Only medium-distance range during day, somewhat greater at night.	“National” broadcasting marine and aircraft communication, direction finding.
Short Waves.	100 to 10	Travel up to ionosphere then back to earth. Conditions for ionosphere reflection vary with time of day and season. Very great distance range.	Long-distance, “international” broadcasting, point-to-point communication, etc.
Very Short, Ultra Short, Super Short, and Extremely Short Waves.	Below 10	Travel just above and over earth's surface only, and for relatively short distances.	Short-distance communication, television, radar systems.*

\* A recent development, whereby the radio energy which is “scattered” at certain levels in the atmosphere is utilised, has extended the range of Very Short Waves to about 1,400 miles, and Ultra Short Waves to about 200 miles. Transmission in the former range is at present limited to telegraphy and telephony communication, whilst the latter is still in the experimental stage.

Although there is no difference in the nature of radio waves of differing wavelength, their actual behaviour during transmission varies tremendously according to their wavelength. In particular, their distance range varies greatly, and thus waves of different length are suitable for different purposes. Table I above roughly classifies them according to their wavelength, and indicates the purpose for which they are used.

The reasons for the variation in the distances reached by waves of different wavelength are briefly as follows: We will assume that the transmitting aerial will radiate waves in all horizontal and vertical directions. Let us consider first the horizontally radiated energy, which, because it travels close to the earth's surface, is known as the “ground wave.” As the ground wave travels along some of its energy is absorbed by the earth itself, and so the wave is weakened and soon tends to die away. The amount of energy so lost increases as the wavelength decreases. Long waves lose relatively little energy in this way, and so their distance range is great. As the wavelength is decreased through the medium waveband the ground losses increase and the waves die away more rapidly, having only a medium distance range, whilst when the short waves are reached the range is reduced to a few tens of miles.

The waves travelling upwards from the aerial go on until they reach the atmospheric region known as the “ionosphere,” which lies between about 60

reaches the longer distance. In the case of the short waves the ionosphere normally acts as an efficient reflector of the upward-travelling waves—the precise manner depending on ionospheric conditions at the time—so the “sky” waves are returned to earth at all times, and consequently reach to great distances. These short waves are therefore most suitable for really long-distance communication of all kinds. Below a certain wavelength, however, the ionosphere no longer

FIG. 1.—WAVE TRAVELLING IN HOPS BETWEEN EARTH AND IONOSPHERE.

acts as a reflector, and these very short waves normally pass right through it. The distance range is therefore that of the ground wave, and so is relatively small. Recently, however, it has been found possible to achieve ranges of about 1,400 miles on the Very Short Waves and 200 miles on the Ultra Short Waves by making use of the “scattering” of radio energy which occurs at certain levels in the atmosphere. This type of

transmission is not as yet much beyond the experimental stage.

**Broadcasting.**—The technical problems involved in broadcast transmission and reception may be summarised as follows: to convert the sound waves of the programme into electric impulses or currents, each characteristic of the sound itself; to convey these impulses without distortion to a radio transmitting station; to superimpose them on the electromagnetic waves being radiated so that they are diffused into space; to pick the waves up again at a distant point and to separate the electrical impulses from them in their original form; to increase them in magnitude in order to compensate for the losses during transmission, and, finally, to reconvert the impulses into sound waves of a similar nature to those originally produced.

Sound waves are set up in the air in the broadcast studio when any "noise"—musical or otherwise—is made, these air disturbances travelling outward from their source at approximately 1,100 feet per second. The character of a sound wave varies in accordance with a number of factors, one of which is its "frequency." If the number of air vibrations per second is large the "pitch" of the note is high, whilst if it is small a low note is produced. The lowest note of a piano, for example, has a frequency of 27·5 cycles per second, and its highest note about 5,600 cycles per second. The range of frequencies which the average person can appreciate is from about 20 to 16,000 cycles per second. A second feature possessed by a sound is its "loudness," which depends upon the *intensity* of the sound waves produced, whilst a third and more subtle characteristic is the "sound quality." It is this which enables us to distinguish between two sounds of the same pitch and loudness, and to recognise, from the distinctive quality, to which instrument of the orchestra each owes its origin. This quality of a sound is due to the fact that it consists, not of a single frequency, but of a mixture of one "fundamental" frequency and several "harmonics." The proportion in which these harmonics are present determines the musical quality or "timbre" of a note or sound.

In broadcasting the aim is to transmit all these features of the sounds without distortion. Although this cannot be done perfectly—because the apparatus is unable to handle the full ranges of frequency or loudness—good-quality transmission can be achieved if frequencies from about 30 to 10,000 cycles per second, and a loudness range covering all but the weakest and most intense sounds, are provided for.

Broadcast studios are rooms designed to suit a particular type and size of programme, the walls—which both reflect and absorb the sound waves—being constructed or treated so as to give that quality to the sounds most desirable and pleasing for the particular type of programme. In addition, there are "General Purpose" studios, whose acoustic characteristics can be varied to suit the programme requirements. Adjacent to the studio there is usually a listening-room, sound insulated from the studio, in which the programme can be heard from a loudspeaker, so that it may be judged as it will sound in a listener's home, as distinct from what it sounds like in the studio. Sometimes it is necessary to add "echo" to the programme, i.e., to give an effect such as would be produced in the interior of a cathedral. This is achieved by taking part of the studio output to a loudspeaker in an "echo room." The sound from this goes echoing round the bare walls of the room, and the result—containing the echo—is picked up by a microphone, and may then be added to the original programme.

Each studio contains one or perhaps several microphones, according to the purpose for which it is used, these being the devices which convert the sound waves into electrical impulses. The type of microphone in most common use to-day is the "ribbon" type, in which a strip of aluminium foil is suspended within a strong magnetic field. Any movement of a conductor in a magnetic field causes an electrical voltage to be set up in the conductor, and when the aluminium "ribbon" vibrates under the impact of the sound waves electrical voltages or impulses are set up in it which are faithfully representative of the sounds which caused them. The outputs from several

microphones may be mixed in any desired proportion by means of a simple electrical arrangement in the listening-room, and the combined output is then taken to the control room of the broadcasting centre.

The control room is the electrical "nerve centre" of the whole system, and through it all the programmes pass. It contains "amplifiers" to which the studio outputs are connected, "mixers" for combining, when necessary, the outputs of several studios or other programme sources, and switching arrangements and "fade units" for maintaining the continuity of the programme. This equipment is followed by the main control amplifier and the control potentiometer, by means of which the intensity of the electrical impulses is kept within the range that can be handled by subsequent apparatus. Finally, there are the amplifiers which transfer the programme to the lines connecting the control room to the radio transmitters.

When the programme originates at an outside point—like a sporting event—apparatus is taken out to the programme site itself, comprising microphones, amplifiers, mixers, and control units, together with means for communicating to the nearest broadcasting centre. The "outside broadcast" is controlled and amplified "on site" and then sent to the control room, where it is fitted into the main programme as if it were from one of the local studios.

No matter where the programme originates, it is eventually sent along the lines connecting the broadcast centre to the radio transmitters, and in this process the impulses soon become weakened by the losses to which they are subject. At intervals of about 40 miles, therefore, a special amplifier, known as a "repeater" is inserted into the lines in order to restore them to a workable level. Arrived at the transmitter, it is found that the high frequencies—corresponding to the high notes of the programme—have become weakened to a greater extent than have the low ones, and in consequence the programme is very much distorted. It is, therefore, passed through an "equaliser" which weakens all the impulses in inverse proportion to their frequency, and thus the distortion introduced by the lines is removed. It is then only necessary to pass them through an amplifier which increases all the frequencies equally and so bring the programme back to a volume suitable for feeding to the transmitter itself.

**Radio Transmitters.**—The first function of a radio transmitter is to generate high-frequency oscillations which, when amplified and fed to an aerial system, will set up electromagnetic waves in space. Its second is to provide some means of "modulating" these waves so that they will carry the intelligence which it is desired to transmit.

The transmitter may operate upon wavelengths varying from several thousand metres to a few centimetres (i.e., the frequency of the oscillations it produces may vary from a few thousand cycles to hundreds of millions of cycles per second) according to the purpose for which it is intended. The form of intelligence transmitted may also vary widely, ranging from telegraphy to broadcast speech and music or television.

In the course of their development radio transmitters have employed many different systems of generating the high-frequency oscillations. Among these may be mentioned the induction coil, the spark transmitter, the Poulsen arc, and the high-frequency alternating voltage generator. All these systems, however, have disadvantages which are not shared by the thermionic valve, and consequently this has gradually superseded them and is now almost exclusively the means used to generate the oscillations in modern radio transmitters.

If a coil of wire is connected in the anode circuit of a valve, and another coil in the grid circuit, the valve can, by means of the electrical interaction between these coils, be made to produce electrical oscillations. By choosing particular values of "inductance" and "capacity" in these circuits the oscillations can be "tuned" to the desired frequency. The "inductance" usually consists of suitably proportioned coils of wire, whilst the "capacity" is provided by means of "conden-

seers," which consist of sheets of metal separated by air or some other insulating material.

Such a circuit, however, exhibits a tendency to change its operating frequency slightly with small changes in the voltages supplied to the valve, and changes in the temperature of the air surrounding the oscillatory circuit. Such changes would, of course, alter the operating frequency, and thus the wavelength, of the transmitter, and, as this is obviously undesirable, steps are taken to control the circuit in such a way as to prevent these changes occurring. Firstly, the oscillatory circuit is usually supplied through a voltage regulator which keeps the voltage nearly constant, despite variations in the voltage incoming to the regulator itself, and it is placed in a small oven whose temperature is maintained constant within very close limits by means of a thermostat; secondly, "crystal control" is applied to the oscillator. Certain crystals such as natural quartz, Tourmaline, Rochelle salt, etc., possess what are known as "Piezo-electric" properties. Very simply, if subjected to mechanical compression or tension these crystals produce an electrical potential difference across certain axes. Conversely, if an alternating voltage is applied to the crystal it will vibrate, and if the frequency of the alternating voltage is close to the natural frequency of the crystal—which is determined largely by its physical dimensions—something approaching mechanical resonance occurs. This mechanical vibration sets up a correspondingly large oscillatory voltage across the crystal, which is applied to a valve and used to maintain the electrical oscillations in the valve and its associated circuit. Since the frequency of oscillation is almost entirely governed by the dimensions of the crystal, a very high degree of transmitter frequency stability can be achieved by using a crystal in this way. The oscillations which are produced by this "drive" circuit (as it is called) are then passed through as many "amplifying" stages as are necessary to increase the power to a level suitable for applying to the aerial. Such oscillations when radiated by the aerial do not themselves convey any intelligence, and the resultant wave is called the "carrier" wave.

To impart the intelligence to the carrier it is necessary to "modulate" this wave with, for example, a broadcast programme. This, as we have seen, is composed of electrical impulses which vary in accordance with the sounds which produced them. Like the output of the drive circuit, the programme signals received over the lines from the studio are amplified until they are of sufficient power to be applied to the modulator valve or modulation transformer, according to the system in use in the particular transmitter. By one of these means these amplified programme currents are made to alter the "amplitude" of the oscillations of the carrier wave. The result is that while the frequency of the carrier wave is unaffected, its amplitude varies in sympathy with the programme impulses it is carrying. The programme impulses are therefore conveyed through space to the receiver, and at the receiver it is only necessary to cause the variations in the amplitude of the received wave to set up electric currents, and these will be an exact replica of those produced by the microphone. Fig. 2 will help to explain the process of modulation; it shows in diagrammatic form: (a) the unmodulated carrier wave; (b) the programme impulses; and (c) the modulated carrier. The method described above is only one way of modulating a carrier wave; another, known as "frequency modulation" (F.M. for short), although more complex, has certain advantages.

In this system the amplitude of the carrier wave remains unchanged, and its frequency is varied at a rate corresponding with that of the programme. Until fairly recently frequency modulation had not been used to any great extent, chiefly on account of the more complicated apparatus necessary. Under suitable conditions, however, a transmitter using this system can offer improved fidelity, greater freedom from interference, and a larger broadcast service area than a comparable amplitude-modulated transmitter. On May 2, 1955, the B.B.C. started the first regular frequency-modulated, very high frequency (v.h.f.) broadcasting service in this country from its new

transmitting station at Wrotham, Kent. This service has brought relief from foreign interference to many listeners living in London and South-east England. The Wrotham transmissions were followed during 1955 by similar services from medium-power transmitters at Pontop Pike, near Newcastle-on-Tyne, and Wenvoe, near Cardiff, together with a temporary station at Penmon in Anglesey. Two further medium-power v.h.f. f.m. stations are expected to be in service early in 1956, one at Divis, near Belfast, and the other at Meldrum, in Aberdeenshire. Further stations are being built, and should be completed in 1956; at the end of the year it is expected that some 84 per cent. of the population of Great Britain will be able to avail themselves of a v.h.f. f.m. broadcasting service.

The modern high-power transmitting station is an elaborate and complicated plant occupying—with its associated masts and aerial systems—many acres of ground. Nowadays most stations draw their power from the public electricity-supply mains, although frequently stand-by generating plant is installed (and in some instances very large-capacity storage batteries from which power can be drawn for limited periods) for use in the event of a breakdown.

(a) UNMODULATED CARRIER WAVE.

(b) MODULATING IMPULSES.

(c) MODULATED WAVE.

FIG. 2.

Power from the mains (or the station's own generating plant) is fed either to motor-generator sets or to transformers and rectifiers, which produce the necessary voltages for operating the transmitters. The "high-tension" supply for a medium-power transmitter is often of the order of 15,000–20,000 volts, nearly one hundred times that of the ordinary domestic lighting mains! Most up-to-date stations have a control desk from which the filament, grid bias, high-tension, and other supplies are controlled, and on which are duplicated all the voltmeters, ammeters, and other instruments necessary to inform the control engineer of the operating conditions of the transmitter itself.

In the early (low-power) stages the valves are cooled by normal heat radiation in the same way as a receiving valve, but as the power handled by the valves increases it is necessary to provide a blast of air or to use water-cooling to carry away the waste heat. The cooling air is drawn from outside, filtered and blown round the valves through ducts specially designed to direct the air where it is most needed (in some instances the air after being heated by its passage over the valves can be used to

warm the station building in cold weather). When water-cooled valves are used the water is circulated through water-jackets round the valve anodes. All the coils, condensers, resistances, and other components associated with the valves are enclosed with them in glass-fronted steel cubicles, the doors of which are interlocked in such a way as to prevent the high voltages being switched on when the doors are open or, alternatively, to switch them off if the doors are accidentally opened while the transmitter is working. This arrangement and other more complicated interlock schemes protect both the engineers operating the station and the equipment itself from accident.

Adjacent to the transmitter and its control desk there is usually a small control room which houses the amplifiers and equalisers associated with the lines bringing the programme from the studios. It is here that the necessary adjustments, described earlier, are carried out before the programme is passed to the transmitter proper.

Individual transmitters may vary very much in detail from the above description, since there are so many different varieties, long-, medium-, short-, or very-short-wave transmitters; some used solely for radio-telegraphy, others for long-distance radio-telephony, for communication with ships at sea, for broadcasting, for television, for radar, and for other purposes.

Some broadcast transmitters are automatic. They are switched on and off by a time switch, and whilst in operation are monitored by automatic equipment which will call attention to any faults which may develop by ringing an alarm at the nearest manned station. In addition, the automatic monitor can, in certain circumstances, change over, or switch off, defective items of equipment without interrupting the service.

**Aerials.**—The function of the aerial is to place the high-frequency oscillations generated in the transmitter in contact with as great a volume of space as possible, so as to permit a relatively large radiation of energy into space. Conversely, a receiving aerial, because it is in contact with a comparatively large volume of space, can absorb a larger amount of energy from the passing wave than the receiver circuits themselves. All radio receivers—except those fitted with a built-in "frame" aerial—should therefore be connected to an efficient aerial in order to obtain the best results.

Transmitting aerials vary considerably in design and construction, according to the wavelengths upon which they are intended to operate and the degree of directivity which it is desired to achieve.

Medium-wave aerials generally consist of an earthed vertical radiator a quarter of a wavelength long, this being the best condition for efficient radiation with such an aerial. Sometimes a horizontal "roof" is added to the vertical part, and a "loading coil" is usually provided by means of which the aerial may be "tuned" over a range of wavelengths. By using more than one vertical aerial it is possible to direct the radiated energy towards a particular area, but the effect is limited. In recent years "mast-radiators" have come into use in increasing numbers. In an aerial of this type the mast itself is mounted upon insulators, and the steelwork used for its construction becomes the radiating system. Such an arrangement is not only economical but also possesses other advantages. For example, by fitting a "capacity top"—a series of arms similar in appearance to the ribs of an umbrella—the electrical characteristics of the aerial, in particular its effective height, may be altered. Thus the aerial may be tuned, and in certain circumstances the shape of its service area can be slightly adjusted, which is sometimes very valuable, particularly in the case of aerials being used for broadcast transmission. Mast radiators are sometimes divided into two parts by an additional insulator inserted into the structure at a chosen height. By feeding the output of the transmitter to the two sections of the mast separately—usually at their junction—the effect is that of an elevated half-wave aerial, and it can be adjusted to extend the fading-free range of the station.

Short-wave aerials are usually unearthed hori-

zontal lengths of wire, half a wavelength long, connected to the transmitter by feeder lines so arranged as to have no effect on the wavelength. Short radio waves are easily "beamed," that is to say they lend themselves to transmission in specific directions. In long-distance transmission this is generally desirable, and it is achieved by increasing the radiated energy in certain directions and suppressing it in others. The energy is concentrated not only in azimuthal directions, but, so that it may reach only the desired reflecting point in the ionosphere, in vertical directions as well. This is usually done by using an aerial "array" consisting of a number of half-wave aerials arranged in rows, in both the horizontal and vertical planes; in general, the greater the number of aerial elements there are, the narrower can the beam be made in both planes. The vertical angle in which the beam is projected is controlled by the height at which the array is suspended above the ground.

In order to suppress the energy in unwanted directions a "reflector curtain" is hung behind the main array and spaced a quarter of a wavelength from it. This "curtain" consists of a similar arrangement of half-wave aerials, but it is not fed with energy from the transmitter. If it is desired to transmit at different times to places lying in opposite directions, special switching facilities are often provided for the arrays. These are so arranged that when a particular aerial has finished transmitting in, say, a northerly direction, it can serve as a reflector for the aerial working in a southerly direction, which had previously acted as a reflector for the north-bound transmission. By such means economies can be effected in the use of materials and ground space.

There are several other varieties of short-wave aerials available, and the precise type to be used for any project is largely dictated by the particular purpose for which it is required and any special circumstances which may be involved.

For television and other ultra-short-wave transmissions it is also usual to employ half-wave aerials, but in these cases the wavelengths are such that rigid conductors may be used. The most important single factor to be considered in this wave range is the height of the aerials above the ground. They should be as high as practicable, as, at these very high frequencies, the waves travel directly through the lower atmosphere, and the greater the height of the aerial the greater the distance range of the transmissions. The most common aerial used in this wave band is the half-wave dipole, which is frequently constructed from rods or tubes, although some transmitting aerials are made from heavy metal strips. For receiving, a rigid vertical rod with a reflector behind it—the familiar "H" aerial—is most commonly used, and increased "gain" in the direction desired is often achieved by the fitting of additional elements in front of the receiving aerial itself. Yet another type of transmitting aerial, suitable for use at very high frequencies, is known as the "slot aerial," and consists of one or more narrow rectangular apertures half a wavelength long in an electrically conductive sheet. In practice, the slots are usually arranged round the periphery of a vertical metal cylinder so as to give a uniform signal in all directions. Each slot is energised by a vertical rod placed just behind it inside the cylinder and connected to the transmitter by a co-axial feeder. Since the actual slot may be filled with an insulating material, such as Perspex, an aerial of this type can readily be made weather-proof, and the mechanical construction is relatively simple.

**Radio Receivers.**—Although the broadcast receiver is only one of the many types of radio-receiving equipment in everyday use, the general principles underlying its operation are common to all radio-receiving apparatus.

As stated earlier, its main functions are to accept the energy picked up by the aerial from the passing radio waves; to separate the low-frequency programme impulses from the high-frequency carrier wave; and, having separated them, to amplify these programme impulses to a power level sufficient to operate the subsequent apparatus, usually a loudspeaker, for reconversion into sound.

**Tuning the Receiver.**—In order that the receiver may respond to the waves sent out by the station it is desired to listen to, and not to those of stations operating on other wavelengths, means must be provided to adjust it to accept signals of one wavelength, and to reject the others. This process is called "tuning" and makes use of the principle of "resonance."

When travelling by bus it is frequently noticed that at a certain speed a particular window will commence to rattle violently; above or below that speed the window is quiet. This phenomenon is caused by mechanical resonance. The window—due to its shape and size and the physical properties of the materials of which it is made—possesses a certain natural frequency of vibration. When the engine of the bus is running at the speed which sets up vibrations in the vehicle at or very near that natural frequency, the window starts to vibrate in sympathy. Now in electrical circuits which are made up of inductance and capacity each individual circuit has a resonant frequency. At this particular frequency the circuit will pass its maximum current, and, like the bus window, if it is "excited," this time by electrical oscillations at or very near that resonant frequency, it will respond readily, whereas it will be almost unaffected by oscillations of a different frequency. In the radio receiver therefore it is arranged, by the process of "tuning," to alter the resonant frequency of the circuit to which the oscillations picked up by the aerial are fed. This alteration can be achieved either by changing the number of turns of wire on the tuning inductance, or by altering the capacity of the tuning condenser, or both. In practice, it is not very convenient to keep changing the number of turns of wire on the coil, so the circuits are generally arranged in such a way that for a particular waveband—say the long waveband—the inductance is kept constant and the capacity of a variable condenser connected across it is varied to effect the necessary changes in the tuning circuit. To make the operation of the receiver as simple as possible it is usual to choose a value of condenser and inductance such that a complete waveband can be tuned by altering the condenser from maximum capacity to minimum capacity. When it is desired to make a larger change in the wavelengths to which the set will respond, the value of the inductance is changed—by switching in another coil, by the operation of the "wave-change" switch. This enables the same condenser to vary the circuit characteristics over yet another range, the wave-change switch usually providing "long" and "medium"-wave ranges and often one or more "short"-wave range. The tuning condenser is operated by turning the tuning knob on the front of the receiver, the precise wavelength, or frequency, to which the set is tuned being indicated on a dial or other indicator suitably geared to the driving spindle of the variable condenser. Some broadcast receivers are equipped with push-buttons for tuning, and these buttons are either arranged to switch in and out different circuits, each tuned to a specific wavelength, or to operate an electric motor geared to the tuning condenser so that the latter is driven round to the required position and then stopped until a different button is pressed.

**Coils and Condensers.**—A very desirable, in fact almost essential, feature of a modern broadcast receiver is high selectivity. This means that it must be able to receive the desired station adequately, but without any overlapping and interference from others. It should be apparent from foregoing sections that if this result is to be achieved, the receiver must respond not to one precise frequency only, but rather to a small band of frequencies on either side of the carrier frequency. This is because the modulation of the carrier by the low-frequency programme impulses causes the radiated energy to be spread over a limited band of frequencies known as the "sidebands." In order that the quality of the received programme shall not be impaired, it is necessary that the receiver shall respond to these sidebands as well as the carrier. A selective receiver tuned to a given point will therefore respond to the desired carrier wave and its sidebands, but not to frequencies outside this range.

One important factor in securing a high degree

of selectivity is the efficiency of the tuning coils, and much care and ingenuity has been devoted to the design of modern coils in order to reduce all the avoidable losses to an absolute minimum. Almost equally important is the actual arrangement of the circuits themselves in the receiver. The use of several tuned circuits operating together is a potent influence in providing the selectivity necessary under modern conditions, when large numbers of transmitting stations are operating simultaneously on closely adjacent frequencies.

As described earlier, such circuits are generally tuned by varying the capacity of a condenser connected across a coil. The variable condensers usually consist of two sets of interleaving metal plates, one fixed and one moveable, insulated from each other by an air space or other insulator. The amount of capacity in circuit is determined by the degree of interleave of the plates, the moving set being controlled by the tuning knob. When several circuits are required to be tuned simultaneously the condensers in each circuit are "ganged" together by mounting them in one rigid assembly holding the fixed plates, and providing a common driving spindle for all the moving plates. The movement of the one tuning knob thus varies all the condensers at once, and so all the circuits are tuned together in one operation.

**Detectors.**—Having made provision to tune the receiver to the incoming waves, the next step is to incorporate within it some means of detecting the intelligence carried by them. This is necessary, because the incoming waves as received, although modulated by the programme, are still at frequencies far too great to be audible to the human ear, even if the loudspeaker could reproduce them. In some way therefore the low-frequency programme impulses must be sorted out from the carrier, and the latter removed. This is the function of the detector. What it does it to produce a low-frequency current in the receiver, a current which varies in sympathy with the amplitude of the waves being received. It does this in the way described below, where the detector is assumed to be a crystal.

Reference to Fig. 2 (c) will show that the low-frequency programme currents caused the variations in the amplitude of the carrier wave. The rate at which the amplitude of the carrier is changed therefore is the frequency of the programme current at any instant, and the amount by which the amplitude is changed is the strength or loudness of the programme. The detector, whether it be a crystal or a small metal rectifier, acts as a one-way device, and so when the high-frequency oscillations produced in the tuning circuit by the modulated carrier are applied to it, current passes freely in one direction, but not in the other. The result is that half of the high-frequency oscillations are stopped, and a series of pulses of high frequency are left, all acting in one direction. The rate of change of amplitude of these pulses is the same as that of the currents which modulated the carrier wave at the transmitter. The diagram Fig. 3 shows the pulses in

FIG. 3.—SHOWING DETECTION PROCESS.

full lines, and the varying mean current which results from them as a dashed line. Now if a pair of headphones is connected across the detector the individual pulses will be of such a high frequency that they will not operate the diaphragms in the headphones, but the mean current indicated by the dashed line is changing much more slowly, and to this slower change the diaphragms will respond. The mean current is, in fact, varying at low frequency, and is the modulation imparted to the carrier wave by the original programme sounds (compare Fig. 2 (b) with the dashed line of Fig. 3), and so the telephone diaphragms, as they respond to its variations, faithfully reproduce the sounds which caused the electrical impulses in the studio microphone.

**The Diode Valve Detector.**—Fleming's original thermionic valve had only two electrodes, and although the addition of more electrodes has increased its usefulness, the original two-electrode type or "diode," as it is called, is still used to-day, being one of the most popular modern detectors. The diode valve consists of the familiar highly evacuated glass envelope containing a fine wire filament and a metal plate called the "anode." If an electric current is passed through the filament it becomes heated and gives off electrons. When the anode of such a valve is positively charged it will attract the negatively charged electrons, which will flow through the valve to the anode and thence through the external circuit, thus producing an electric current. If, however, the anode is negatively charged it ceases to attract the negatively charged electrons emitted by the filament, and the current stops flowing. From this it will be clear that, if the high-frequency voltages set up in the receiver circuits by the radio waves are applied to the anode of a diode valve, current will flow through the valve during each positive half-cycle, while during each negative half-cycle the current will stop. Such a valve, therefore, behaves in a manner identical to the crystal detector already described, suppressing every other half-cycle of the high-frequency currents and allowing the remainder—all flowing in one direction—to pass. The resulting uni-directional current impulses produce a "mean valve current" varying at low frequency in the same way as that described for the crystal, and this low-frequency current can be used to actuate the diaphragms of the headphones.

**The Triode Valve.**—This valve, as its name suggests, is one which contains three electrodes, and was developed by Lee de Forest from Fleming's original diode.

It has a filament and an anode like the diode, but in addition it is fitted with a "grid." This grid is usually in the form of a fine wire mesh placed between the filament and the anode. Normally the electrons leaving the filament can pass through this grid without interruption, and reach the positively charged anode. If, however, the grid has a negative potential applied to it, it will restrict or even stop the flow of electrons to the anode, depending on the strength of the negative potential. This important property of a triode can be used to amplify weak signals so as to render them strong enough to be useful. If this amplification—the principle of which will be described later—is used before the detector stage it is called high-frequency or radio-frequency

receiving circuits are very weak, as they are only those set up by the incoming waves. If the ends of these circuits are connected between the grid and filament of a triode valve the oscillating voltages set up in them by the incoming waves will make the grid alternatively positive and negative. Now if the grid is positive it attracts electrons; if negative it repels them, thus the anode current, or current passing through the valve, is caused to rise and fall in sympathy with the incoming signals. These incoming signal voltages are thus enabled to control the much greater power flowing between anode and filament, which is derived from local batteries or from the electric mains.

Fig. 4 explains this action more clearly. The sloping curve on the left is a typical valve characteristic, and consists of a graph showing the relationship between anode current and grid voltage.

Let us suppose that the normal grid bias applied to the valve whose characteristic is shown in Fig. 4 is 1.5 volts. It will be seen that with this amount of bias the anode current will remain steady at a value of about 3.5 milliamps., corresponding to point A on the characteristic curve. Now the currents set up in the receiver circuits by the passing radio waves are very much less than this. So if the voltage produced by them is applied to the grid, and, for example, varies the grid potential from zero to 3 volts negative, as indicated by the curve below the base line, the anode current will be varied between point B and point C on the curve. Thus we have a varying current many times stronger than the original, yet, as will be seen from the curve on the right, varying exactly in sympathy with the original.

If a coil is connected in the anode circuit the rising and falling current passing through it produces a rising and falling magnetic field, which, in turn, sets up an oscillating voltage across the coil. Since the changes of anode current are greater than the original changes set up by the radio waves in the first circuit, the voltages appearing across the anode coil will be correspondingly greater, and thus the original signals have reproduced themselves—via the valve—in a considerably amplified form.

A similar type of valve and circuit arrangement may be used for amplifying the low-frequency voltages obtained after detection, thus strengthening them to a power level sufficient to operate a loudspeaker.

The triode can also be used as a detector if a suitable circuit arrangement is employed. One method—known as the "anode bend" method—is to arrange for the grid-bias voltage to restrict the anode current to the point where the curve bends sharply—indicated by point X in Fig. 4. When biased to this point, only grid voltages swinging in a positive direction are able to increase the anode current, negative swings having no effect upon it. In this way the alternate negative half-waves are suppressed, and the circuit behaves in much the same manner as that of the diode described earlier and illustrated in Fig. 3. Yet another method is to insert a fixed condenser in the grid lead, and a resistance—known as the grid leak—between grid and filament.

**Multi-Electrode Valves.**—So far we have dealt only with the simpler types of valve—the diode and the triode—but nowadays there are many more complicated types. These have been evolved by the introduction of additional electrodes into the earlier valves in order to improve their amplifying properties for both high and low frequencies, and for various other purposes.

One of the deficiencies of the triode valve is that when used as a high-frequency amplifier there is a limit to the amount of amplification that can be attained owing to the liability of energy being fed back from the anode to the grid—as it were through a capacity—thus causing the arrangement to become unstable. This tendency can be overcome by interposing an extra grid between the anode and the ordinary control grid, and valves of this type—known as the "screen-grid"—are often employed for high-frequency amplification. The extra grid, which is kept at a steady potential somewhat lower than that of the anode, screens the latter from the control grid, prevents the feed-

FIG. 4.—SHOWING RELATION BETWEEN GRID VOLTS AND ANODE CURRENT.

amplification, and if used after the detector stage it is called low-frequency amplification.

Both types of amplification are frequently employed to increase the "sensitivity" of a modern radio receiver. The currents flowing in the first

back of energy from the anode to the control grid, and so permits greater amplification to be achieved without instability.

For low-frequency amplifiers the "pentode" valve, having five electrodes, is commonly used. This valve is capable of handling a large amount of power and has a high amplification factor; it is therefore particularly suitable as a final amplifier in a receiver, where it can be utilised to provide a relatively large amount of power for the loudspeaker. Five electrode valves of a different type are also employed for high-frequency amplification.

It is also common practice to perform the functions of more than one valve within a single glass bulb—i.e., one valve envelope may, for example, contain assemblies to amplify high-frequency oscillations, generate local oscillations, and detect. The diode detector is often included within the bulb of another valve: sometimes there are two diodes—one to act as a detector and the other for automatic volume control—as well as a triode assembly, all within the one bulb. In super-heterodyne receivers it is necessary to generate local oscillations in the receiver itself and to mix these with those set up by the incoming signals, and for this purpose several different valve types having various arrangements of electrodes are in use.

**The Super-Heterodyne Receiver.**—Most modern broadcast receivers are of the "super-heterodyne" type, in which the "heterodyne" principle of reception is employed. In this system local high-frequency oscillations are generated within the receiver, but of a slightly different frequency from those being received. The two sets of oscillations are allowed to "beat" together, and the result is that, after detection, a third set of oscillations of yet another frequency is produced.

The advantages of the super-heterodyne receiver are that the necessity for tuning all the circuits of the amplifiers to the wavelength or frequency of the incoming wave is avoided, and most of the amplification required can be performed at one fixed high frequency, no matter what wavelength is being received. This permits the amplification to be carried out in a particularly efficient way, since the circuits can be designed to work at maximum efficiency when only a single frequency has to be handled; furthermore, the system greatly facilitates interference-free reception.

The super-heterodyne receiver uses an oscillator so arranged as to be always mistuned to the frequency of the incoming signals by a certain fixed amount, so that "beats" at, for example, 465 kilocycles per second are produced, irrespective of the frequency being received. These beats are detected and passed to the anode of a valve, where oscillations at 465 kilocycles per second are established. This frequency is termed the "intermediate frequency," and the circuits of the succeeding amplifying valves remain constantly tuned to this one frequency. If a broadcast programme is being received, then the amplitude of the intermediate frequency oscillations varies at audio-frequency, and a second detector is required to sort out the audio-frequencies of the programme from the intermediate frequency, so that they may be fed to the loudspeaker.

**Automatic Volume Control.**—As has already been explained, the anode current flowing through a valve may be limited by the application of a steady negative voltage to its grid. This is called grid "bias," and it may be derived from a battery or from the voltage developed across a resistance in the circuit. In modern receivers this characteristic is made use of to counteract "fading," i.e., the rise and fall in the strength of the incoming waves due to variations taking place during their journey from the transmitter to the receiver. A diode valve is incorporated in the circuits following the intermediate-frequency amplifier and supplied with voltages at the intermediate frequency. These are then detected and fed back to the control grids of the pre-detector amplifiers. Thus, when the strength of the incoming signals rises above normal a negative voltage is applied to the amplifying valve control-grids, and so their amplification is reduced. Conversely, when the

incoming signal strength drops below normal, less negative voltage is fed back from the diode to the amplifier-valve grids, their amplification is increased, and more voltage is delivered to the second detector. In this way most types of fading can be overcome, or at least considerably reduced, and the input to the low-frequency end of the receiver maintained at an approximately constant level.

**Power Supplies.**—Portable radio receivers and certain sets intended for use, for example, in ship's lifeboats or in remote country districts, derive their power from batteries, but the vast majority of modern receivers are fed from the electricity-supply mains. There are two kinds, alternating current (A.C.) and direct current (D.C.). Alternating current mains supply is nowadays almost universal, and in the A.C. mains-operated receiver power is supplied to a transformer which changes the voltage to values appropriate for the "high-tension" and "low-tension" supplies for the valves. In the case of the "high-tension" supply the power has to be converted to direct current (D.C.), and this is done by a rectifier, which may be a metal-rectifier, a mercury-vapour rectifier, or a double-diode valve. Like the detector any of these rectifiers produces a series of unidirectional pulses of current. These pulses require "smoothing," and this is carried out by means of condensers and a choke coil, the final smoothed D.C. supply being fed at a suitable voltage to the anodes of the receiver valves.

Receivers working from D.C. mains cannot be fitted with transformers, and their circuits have therefore to be designed to operate at voltages slightly below those commonly found in D.C. mains supplies. Resistances are used to provide voltages below those of the mains, and smoothing equipment is incorporated to remove any "ripple" present in the supply, as this, unless smoothed out, would produce unwanted noises in the programme heard from the loudspeaker.

The valves may be heated directly or indirectly, and the filaments of the directly heated type, or the heaters of the indirectly heated type, are supplied from low-voltage windings provided for the purpose on the mains transformer in the case of A.C. operated sets. In the case of sets operated from D.C. mains they are supplied through high resistances which "drop" the mains voltage to the appropriate value.

## TELEVISION.

**Historical.**—So important is the sense of sight that men have, from very early times, been constantly trying to increase its range and to enlarge its power. It is not surprising, therefore, that many of the scientific discoveries that have gone to make television possible took place before radio itself had become a practical proposition. One of the most significant of these was the result of a pure accident, which led to the discovery by Willoughby Smith in 1873 that the electrical properties of selenium vary according to the amount of light to which it is exposed. This discovery pointed to the possibility of converting light waves into electrical impulses.

Here certainly was the first requirement for the transmission of sight by radio or by wire, but it was evidently by no means enough, for it did not show how all the infinite variations of light and shade in a scene were to be transmitted to a distance and yet presented to the viewer's eye simultaneously. It was evident that the scene would have to be broken down into a number of small elements, each of which could be transmitted separately and then reassembled at the receiving point. The thing must be done so rapidly as to deceive the eye into thinking that it sees all the elements at once, and furthermore, consecutive pictures must be built up so rapidly as to give the eye the impression that it sees a continuous scene.

A means of doing this was provided by Nipkow in 1884, when he invented his famous scanning disc, and later Weiller invented the mirror drum for the same purpose. Such mechanical devices as these held the field for many years, and in 1923

Baird in this country and Jenkins in America were both using them for the experiments which, in 1925, led to the successful transmission of shadows and simple outlines. It was not until 1926, however, that the first practical demonstration of television, as we understand it, took place. In London, on 27th January of that year Baird transmitted by radio moving pictures of living human faces over a short distance.

In 1927 transmission of a picture by wire over a distance of 250 miles took place in America, and the demonstration was repeated by radio shortly afterwards.

In 1929 the B.B.C. gave facilities to Baird Television Ltd. for experimental television transmissions. The programmes, which originated in Baird's studio in Long Acre, were radiated by the B.B.C.'s Oxford Street (2LO) station on a wavelength of 365 metres. These transmissions used 30 scanning lines to the picture, and 12½ pictures per second were transmitted. The Oxford Street station radiated vision only, but in 1930 this low-definition television service was transferred to the B.B.C.'s new London Regional transmitting station at Brookmans Park, and sound was added to the programmes. The 30-line transmissions were of sufficient technical interest for the B.B.C. to equip one of the studios in Broadcasting House, London, with Baird apparatus, and this was brought into operation in 1932.

At this time much thought and energy was being expended upon the problem of improving the "definition" of the television pictures, and it was becoming apparent that a satisfactory standard could not be reached using mechanical scanning methods. Attention was returned to an idea which had been put forward by A. A. Campbell Swinton as long ago as 1908, when he had suggested a television system using cathode-ray tubes at both the transmitter and receiver. He had expanded this idea in his presidential address to the Röntgen Society in 1911, when he envisaged a special type of cathode-ray tube at the transmitter—the forerunner of the television "camera" of to-day. At the same time he described in detail arrangements for moving the beams of the transmitting and receiving tubes exactly in synchronism. The great advantage of this idea was that by using an agent like the cathode-ray, which possesses practically no weight or inertia, and is, therefore, capable of being swung about with tremendous speed and accuracy, the great difficulty with the mechanical systems of securing the extremely accurate yet rapid motion of the scanner, disappeared.

By 1934 "cameras" on these principles had been developed both by the Marconi-E.M.I. Co. in this country and by Zworykin in America, and it seemed possible that a television service with markedly improved definition might be practicable. In May 1934 the Postmaster-General appointed a committee under the chairmanship of Lord Selsdon to report on the relative merits of the various systems then being developed.

On the recommendations of this committee the B.B.C. was entrusted with the task of erecting a television transmitting station at Alexandra Palace, London, and Baird Television Ltd. and the Marconi-E.M.I. Television Co. Ltd. were invited to tender for the supply of apparatus for their respective systems. These two systems were operated alternately, the Baird system on 240 lines, 25 pictures per second with sequential scanning; the Marconi-E.M.I. system on 405 lines, 25 pictures per second with interlaced scanning, giving 50 frames per second. The Radio Exhibition at Olympia in August 1936 was the occasion of the first public transmissions by the two systems from Alexandra Palace on an experimental basis, and the station recommenced transmissions with a series of trial programmes in October, these lasting for two hours daily.

The Alexandra Palace Station was formally opened by the Postmaster-General on 2nd November 1936, and this marked the start of the world's first public high-definition television service. Programmes were radiated for two hours each day, the two alternative systems being used during alternate weeks. On 6th February, 1937, the Postmaster-General announced that the Television Advisory Committee, as a result of the experience gained from these transmissions,

recommended the adoption of a single set of standards—those of the Marconi-E.M.I. Co. Accordingly, from 6th February, 1937, this became the standard system for British Television, and the service from Alexandra Palace continued until the outbreak of war, when the station closed down. Alexandra Palace reopened to provide a television service for the London area on 7th June, 1946, using the pre-war standards.

Since that date the B.B.C. has brought several new high-, medium-, and low-power television transmitting stations into operation, and at the end of 1955 its television service was available to 93 per cent. of the population of Great Britain. Many other stations are, of course, operating in America, Europe, and elsewhere.

The London Television Station was moved to Crystal Palace, Sydenham, in March 1956, when its power was increased. This and other measures will increase the B.B.C.'s television service coverage still further.

The B.B.C. has in existence plans for the provision of alternative programmes and for the development of a system of colour television. The Television Advisory Committee has recommended, however, that any colour television system which may be used in the future should be so arranged that its transmission would provide black-and-white pictures on receivers not designed for colour. To facilitate development work on the many problems associated with a colour-television transmission system the B.B.C., in conjunction with the British Radio Equipment Manufacturers Association, radiated a series of colour test transmissions from its Alexandra Palace station in the autumn of 1955.

In addition to the television programmes provided by the B.B.C., separate programmes have, since September 22, 1955, been radiated by the Independent Television Authority from its station near Croydon, Surrey. The I.T.A. plans further stations in other parts of the country which will increase the coverage of the Authority's programmes.

**The General Principles.**—There are certain fundamental differences between the broadcasting of sound and television, and these differences are mainly concerned with the senses by which the broadcasts are perceived. The ear, with which sound broadcasting is concerned, will respond to a single note, but if a chord is struck it does not differentiate between each individual note, but presents to the brain a composite sound made up of all the notes in the chord. In all cases where there is a combination of sounds, such, for example, as in speech or music, it is a complex wave combining all the sounds together which excites the ear-drum and is passed to the brain.

The sense of sight, however, is completely different in its method of operation, and to understand the problems of television it is necessary to consider the action of the human eye. Basically the eye consists of a lens which projects an image of the scene before it upon the retina, a light-sensitive screen at the back of the eye. The retina is made up of several millions of tiny light-sensitive elements, each quite separate and distinct from its neighbours, and each separately connected to the brain by an individual fibre in the optic nerve. Thus the eye is a very complex organ, and it is able to pick out numbers of tiny details from a scene and convey each detail separately and simultaneously to the brain. It does not send a blend of different points of light and shade in the same way that the ear sends a blend of different sounds; if it did the brain would receive a completely unintelligible blur. From this it will be seen that a television system which transmitted a mixture of detail would be useless; it must transmit all the details in a scene separately, yet almost simultaneously, and re-assemble them at such a speed that the eye cannot observe the building-up process. The photo-electric cell reacts to light in a manner similar to the light-sensitive elements of the eye, and would therefore reproduce picture details as electrical impulses, but in order to produce a picture having good definition it is necessary to transmit nearly a quarter of a million separate details. As it is obviously out of the question to use such a large number of cells,

each requiring a separate radio transmitter and receiver, to convey the information, some artifice is necessary to make television practicable. The one used is known as "scanning." This process, which is carried out in the television camera, consists of dissecting the scene into a large number of small pieces, rather like the dots visible in a newspaper reproduction of a photograph. Each one is then transmitted separately, and they are re-assembled at the receiver so rapidly that the eye is tricked into believing that it sees the whole picture at the same time.

In the scanning process the picture is divided up into a large number of horizontal lines, each line consisting of a number of the small pieces just mentioned, and the detail in each line is detected by the scanning beam and faithfully reproduced by a similar beam at the receiver. The scanner also transmits "synchronising pulses," which tell the receiver when to start each new line and each new "frame" or picture. As the eye normally takes about  $\frac{1}{16}$  of a second to register a scene, any happening taking less than  $\frac{1}{16}$  of a second is not properly observed. Thus, if successive pictures are built up with sufficient rapidity the fact that they are separate pictures is not conveyed to the brain. The ordinary cinematograph relies on this principle of "persistence of vision" to create the impression of continuous movement.

The television standards used in Great Britain are based on the transmission of twenty-five complete pictures every second, each picture being composed of 405 horizontal lines. The twenty-five pictures per second are not in themselves sufficient to avoid "flicker," and this is overcome by using "interlaced" scanning. In this system the scanning beam first passes over all the odd-numbered lines from top to bottom of the picture, and then returns to the top and scans all the even numbered lines. The two "frames" thus produced mesh together to form the complete picture but as the frames are transmitted at the rate of fifty per second, there is no noticeable flicker.

Let us now consider some of the apparatus which makes television possible.

**The Television Camera.**—Although there are several different types of television camera in use at the present time, they all make use of a lens system to produce an image of the scene before the camera upon a photo-electric plate. Probably the simplest one to understand is the original "Emi-tron" camera, a simplified diagram of which is shown in Fig. 5. It will be seen to consist of a highly evacuated glass tube with a large bulb at one end. This bulb contains the mosaic screen (a) upon which is focused, by means of the lens (b), an image of the scene to be transmitted, the light rays passing through the "window" in the bulb. The mosaic screen consists of a sheet of insulating material backed by a metal plate. On the front of the screen is the mosaic itself, which is made up of several thousands of minute light-sensitive elements—each virtually a tiny photo-electric cell—every one of which is electrically separated from those surrounding it. Each of these little cells

FIG. 5.—TELEVISION CAMERA.

takes up an electric charge proportional to the amount of light falling upon it, and thus the mosaic as a whole acquires an "electrical picture" of the scene. In the tube below the bulb is situated the

"electron gun" (c), which aims a finely focused beam of electrons at the mosaic. The deflector coils (d), near the neck of the tube, cause the beam of electrons to move across the mosaic in a series of horizontal lines, first the odd-numbered lines then the even-numbered lines, as mentioned earlier. As the electron beam passes over each of the "cells" of the mosaic, the cell is discharged and, as a result of this, a series of minute electrical impulses is induced into the metal back plate of the screen, each impulse being proportional to the amount of light falling upon the cell from which it emanated. These impulses are extracted from the tube, along the wire which passes out of it. In this way the picture is taken from the camera spot by spot and line by line as a series of electrical impulses. These impulses are amplified and have added to them the "line-synchronising" and "frame-synchronising" pulses, and are finally used to modulate the carrier wave of the vision transmitter, which carries them through space to the receiver.

**The Television Studio.**—As with sound broadcasting there are several intermediate stages between the camera and the transmitter. In this country the studios operated by the B.B.C. at Alexandra Palace and Lime Grove contain up to four cameras each, and their outputs are taken to the "vision" mixer panel in the vision control room associated with each studio. In this room the pictures viewed by each camera (and sometimes a picture obtained from a "film scanner") are displayed on picture monitors in front of the producer. As the programme proceeds he and his assistant select the particular camera or film scanner output to be transmitted. They can make an instantaneous change from one picture to another, fade one out and another in, or superimpose one upon another according to the programme requirements.

The film scanner is a device which allows cinematograph film pictures to be included in television programmes either for effects purposes or even for a full-length item such as the Television News-reels, in much the same way that the gramophone pick-up allows records to be used in sound broadcasts.

The outputs from the individual studio control rooms are passed through a central control room which performs a similar function to that of its sound counterpart. In addition, means are provided for adjusting the technical quality of the pictures. From the central control room the vision signals are fed to the distribution network linking the studio centres with the transmitters.

**Television Distribution Network.**—This is the apparatus employed for conveying the television programme from the studio to the distant transmitters, and in this country the G.P.O. provide and maintain this equipment. Since the frequency range of picture signals is very much greater than that necessary for sound broadcasting, different and more complex apparatus is required. Cables are used for conveying the picture signals from London to Birmingham, although a radio-link is also available in case of need. The former are of a type known as "co-axial" cables, and are specially designed to carry very high frequency currents. Since the losses are greater at vision than at sound frequencies, repeater stations have to be closer together than would be necessary for sound circuits. Co-axial cables are also used between Birmingham and Manchester and London and Cardiff. The programme for the Kirk o' Shotts station in Scotland is relayed from Manchester by a series of radio links.

In the case of some stations, such as Rowridge in the Isle of Wight, Meldrum near Aberdeen, Divis in Northern Ireland, and Norwich, the vision programme from one of the high-power transmitting stations is received by the G.P.O. on specially designed receiving equipment. It is then passed either directly over a short length of cable or over one or more radio links to the transmitting station.

**The Television Transmitter.**—The principle of the television transmitter is similar to that of transmitters used for sound broadcasting, except

for certain special features, and for the fact that it operates on very much higher frequencies. In order to convey the extraordinarily large number of impulses which go to make up the vision information, the frequency band required for the radiated energy is much wider than for a sound transmission, and this large band-width of about 5 Mc/s. (5 million cycles per second) can only be provided in the very high frequency bands. The television transmitting stations at present operating in Great Britain occupy the frequency band 41-68 Mc/s. and 174-216 Mc/s., Bands I and III respectively.

As explained earlier, the use of these very high frequencies limits the range of the transmitters, and consequently good reception is usually obtained only out to a distance of about 50 miles, although satisfactory pictures are often obtained beyond this distance under favourable conditions. The bands mentioned above are divided into channels, Nos. 1-5 in Band I and Nos. 6-13 in Band III. Each of these channels carries, or will eventually carry, a television programme—although not all channels will be receivable in all districts—and in some cases transmitters widely separated geographically may share the same channel. For example, the B.B.C. transmitters at Kirk o' Shotts in Scotland and Rowridge in the Isle of Wight share channel 3, whilst the I.T.A. transmitter in London will eventually share channel 9 with its counterpart in Lancashire.

**The Television Receiver.**—So that viewers may select the channel or channels appropriate to the districts in which they live, most modern television receivers are fitted with some form of tuning device covering all thirteen channels in Bands I and III. There is, of course, no point in providing continuous tuning as is commonly done in sound receivers. The vision and sound signals from the transmitters are received by a single aerial, but, owing to their being on different frequencies they are separated by the tuned circuits in the receiver, and fed to the vision and sound sections of the receiver respectively, the sound section following normal broadcast-receiver practice. The vision signals are amplified in much the same way as that described for sound broadcasting, and are ultimately applied to the circuits controlling the cathode-ray tube. This consists of an evacuated glass tube containing an electrode which, when heated, emits electrons. The electrons are accelerated and focused into a very thin beam, which can be deflected in vertical and horizontal planes by coils provided for the purpose. Beyond these coils the glass tube is splayed out, and its end is flattened so as to form the viewing screen, the inside of this part being coated with a very thin layer of fluorescent material which glows when bombarded by the electron beam. The brilliance of the glow is proportional to the number and speed of the electrons striking it. The amplified vision signals are caused to vary the strength of this beam, and it is made to move across the screen in horizontal lines one below the other, this movement being controlled by the "line-synchronising pulses," which are added to the vision signal before transmission. It will be seen, therefore, that as the beam moves across a particular line it causes the fluorescent material on the end of the tube to glow more or less brightly according to the strength of signal which the cathode-ray tube receives, and as this signal is originally derived from the impulses from the camera tube, the light and shade of the line varies according to the light and shade of the corresponding line of the scene which the camera is viewing. In this way the original picture is re-assembled spot by spot and line by line. At the end of each picture or "frame" the frame-synchronising pulse deflects the electron beam back to the top line, so that it is ready to trace out the succeeding frame.

The size of the picture in "direct-viewing" receivers is, therefore, decided by the size of the cathode-ray tube, and although pictures up to 21 inches across can be obtained by direct viewing, tubes which give pictures of this size are exceedingly costly. As, however, the demand for large pictures is considerable, a different type of receiver has been produced to meet it. Known as the "projection" receiver, it uses a small cathode-

ray tube having a screen only about 2½ inches in diameter, but arranged to provide a very bright picture. The light from this small tube is passed through an optical system of mirrors and lenses and thrown on to a translucent screen. In this way the picture on the screen can be made very much larger than that on the actual tube by purely optical means.

The above description of the elements of the television system is, of course, a very brief and simplified one, and there remain several aspects and developments of television that we can do no more than mention. The technique for covering outside television broadcasts, for example, is highly developed in this country, though it follows, in general, along the lines of that described for giving broadcasts from the studio. On the Continent standards different from the British 405-line pictures are in use (441, 625, and 819 lines per picture), and this fact has complicated the international exchange of television programmes. Nevertheless, the B.B.C. has developed means for overcoming this difficulty, and in 1952 pictures from the French system were relayed by the B.B.C., whilst the B.B.C. television broadcasts of the Coronation were relayed over the systems of several Continental countries. Frequent exchanges of television programmes with countries on the Continent now take place, and the first part of a permanent television link between London and Europe—a two-way co-axial cable link between London and St. Margaret's Bay—is already in use. Considerable success has been achieved in the field of colour television, and it seems possible that this development may reach the public in the not too distant future. Thus it will be seen that tremendous advances have taken place in the television field since Baird transmitted the first television picture only thirty years ago.

## RADAR.

**Historical.**—In September 1939 Britain's Fighting Services already had in regular operation a new radio technique, by means of which it was possible to detect the approach of hostile aircraft, to plot their positions, and to follow their movements, and by the aid of which the defending forces could be rapidly brought into contact with them. Though the principles of this device were well known abroad, Britain was the first country in the world to evolve a practical system of radar and to put it into regular operation.

The original English name for the technique was "Radiolocation," a term which well describes the process, but, during the war the "synthetic" word "Radar" was adopted from America, a word which we are given to understand is derived from the phrase "Radio Detecting And Ranging."

As in the case of so many of the inventions primarily developed for the purpose of waging war, many useful applications have been found for radar in times of peace, and, in particular, it has proved of great service as an aid to aerial and marine navigation.

The basic principle of radar is very similar to that of sight. We switch on a light in the dark, and we see an object because the light waves are reflected from it and return to our eye, which is able to detect them. Similarly, the radar station sees an object because the invisible radio waves sent out from the transmitter are reflected from it and return to the receiver, which is able to detect them.

The utilisation of radio waves for the detection of reflecting surfaces began with the classical experiment of Dr. (now Sir) Edward Appleton in 1925, which he conducted in order to demonstrate the existence of the Heaviside layer in the upper atmosphere. Then two American scientists found a somewhat different way of doing the same thing—they sent short, sharp "pulses" of radio energy up towards the sky, and found that the Heaviside layer reflected them and sent them down again so that they returned to earth as echoes.

The development of these methods of atmospheric-layer location into a radar system for the detection of smaller objects was only a matter of time, and in this country was placed in the hands of a team of scientists headed by Sir Robert Watson Watt. An experimental station was set up on the East Coast, and soon it became possible to see, on a cathode-ray tube, a clear image of an aircraft flying many miles beyond the range of ordinary vision, and to determine with good accuracy its position in space. Next the process had to be reduced from a scientific experiment to a common routine measurement, capable of being performed by relatively unskilled personnel, whilst equipment had to be produced capable of standing up to the wear and tear of continuous operation under Service conditions. As has been said, all these things were accomplished before war began, whilst during its course developments took place which tremendously improved the methods and instruments used.

**Principles.**—The essential difference between radar and the older methods of radio position finding is that with radar no active co-operation on the part of the located object is required. Radio waves are sent out from the radar station and, being reflected or scattered by the object whose position is desired, some of them are returned to the radar station, which is then able to tell the direction and distance of the object from which they were reflected, and, in the case of an aircraft, the elevation angle as well.

All that is necessary for this to happen is that the object to be located shall be of a material possessing different electrical properties from those of the medium surrounding it, in which case, when a radio wave impinges on it, part of the energy is scattered at the surface of the new medium. What happens is that the wave sets up electric currents in the material, and these re-radiate energy, so that the new material behaves like a small transmitter. Fig. 6 will help to make the

FIG. 6.—RADAR SYSTEM.

matter clear. Note that the reflected waves go out in all directions, but that some part of the energy is returned in the direction from which the wave has come. It is thus received at the radar station again, and from it is obtained the desired information about the object from which it was reflected.

A radar station consists of a transmitter and receiver working usually on centimetre wavelengths, and employing directional aerials which concentrate the radiated energy in the form of a sharp beam. The transmitting aerial can be swept around so as to cover different azimuthal and vertical directions, and the receiver aerial also sweeps around so as to receive only from the direction in which the transmitted beam is being sent.

The energy is sent in very short bursts called "pulses," and the receiver output is connected to a cathode-ray tube, upon whose screen the received pulses appear, as in Fig. 7. It is so arranged that as a pulse is sent off the fluorescent spot starts its sweep from the left of the tube, at O. A certain time will elapse before the reflected pulse is received, during which time the fluorescent spot is moving to the right (towards A) at a certain speed, and a bright line therefore appears on the

screen. When the reflected pulse is received it is made to produce a deflection of the spot such as will produce a pattern like P in Fig. 7, and the position at which the pulse appears, as measured from the left, depends upon the time taken for the pulse to travel to the "target" and back, in other words upon its distance away. As we

FIG. 7.—RADAR DISPLAY.

know that the speed at which the pulse travels is substantially 186,000 miles per second and as the speed at which the spot travels is also known, its sweep across the tube can be marked in a scale of miles, and the distance of the "target" read off directly.

The distance thus indicated is only one of the pieces of information necessary in order accurately to plot the actual position of the target. It is necessary also to ascertain its direction or azimuth, and, if the target be an aircraft, its angle of elevation above the horizontal, as well. The means for obtaining these vary somewhat with the wavelength used, but in most modern radar installations they are determined by training the receiving aerial most accurately in the direction from which the received pulses are coming, a fact which is indicated by maximum deflection of the spot on the cathode-ray tube. Then the azimuthal direction and angle of elevation are read off from horizontal and vertical scales, and, the range being observed from the position of the pulse along the tube, the position of the target in space is given.

**Radar Developments.**—The above is a brief outline of the basic principles of radar, and of its use in determining the position of a distant object, such as an aircraft or ship. Many variations and developments of the original idea have taken place, some of which have tremendously useful applications of a peace-time character. One or two of these may now be mentioned.

Quite early there was developed a special type of cathode-ray tube known as the "Plan Position Indicator" or P.P.I. In this the fluorescent spot is caused to start in the centre of the screen and to sweep outwards to the edge, but at the same time to revolve about the centre so that it covers the whole screen perhaps twenty times a minute. Used in conjunction with aerials which rotate in synchronism with the spot, this causes located objects to appear on the screen in their true position relative to that of the radar station, whose position is represented by a mark at the centre of the screen. Fluorescent screens with a long "afterglow" are used, so that the brighter spots indicating the located objects persist on the screen until the spot sweeps over them again.

A further development of this idea takes the form of a compact radar equipment for use on ships or aircraft, by means of which a kind of television picture of the area surrounding the ship, or that below the aircraft, is shown upon the screen of the cathode-ray tube. As fitted on ships the equipment consists of a radar transmitter and receiver working on centimetre wavelengths, with a small aerial which radiates a beam of energy, and which rotates in synchronism with the fluorescent spot of the P.P.I. tube. As the aerial rotates the beam sweeps over a large circle of territory corresponding to the size of the screen of the tube, the centre of which represents the point at which the ship is located. Anything that stands well up above the surrounding territory sends back strong reflections, whilst flat portions do not. Thus the surrounding sea appears black on the screen, ordinary level soil sends back weak

reflections which cause the screen to glow faintly, but buildings and other structures, coast-lines, ships, and other outstanding features send back strong reflections and the tube glows brightly. Since the receiving aerial is at any instant "seeing" only that part of the landscape being illuminated by the beam, and since the fluorescent spot is, at the same instant, moving over the appropriate part of the screen relative to the ship at the centre, every reflected echo appears at the correct position upon it. Thus a "map" of the surrounding territory appears upon the screen showing all the prominent features of the landscape. It may be imagined how useful this can be in marine or aerial navigation, for it enables the navigator virtually to see through darkness or through fog, and to observe with clarity those objects surrounding him which are dangerous to navigation under conditions when they would

running across the line joining the two stations. An instrument on the ship somewhat like an ordinary electricity-meter continuously records the maxima and minima passed through as the ship moves along, so that, when consulted by the navigator at any time it tells him the number of the "lane" which he is in. A third transmitter, whose waves also interact with those from the first produces another independent pattern of "lanes" which criss-crosses the first pattern, whilst a second instrument on the ship continuously records the ship's position in this pattern, and tells the navigator the number of the "lane" he is in within the second pattern.

Actually the "lanes" are divided into numerous subdivisions, which are indicated by the numerical indications of the two meters. In order to fix his position the navigator merely reads off the number indicated by the first meter and that indi-

FIG. 8.—THE DISPLAY SCREEN OF A SHIP'S "RADIOLOCATOR" PRODUCED BY THE MARCONI INTERNATIONAL MARINE COMMUNICATION CO., LTD.

The ship is in the Straits of Messina, its position being indicated by the white dot, and its direction of heading by the white line.

otherwise be totally invisible to him. This apparatus is of particular use when approaching or traversing a tortuous channel or estuary, and furthermore, since it permits of the observation of other mobile objects, it is of great help in the avoidance of collisions. Fig. 8 depicts the sort of display which appears upon the radar screen of a ship proceeding up a restricted channel, the instrument in use being the Marconi Company's "Radio-locator," and the ship's position being indicated by the dot in the centre, and its direction of heading by the thin white line.

A further class of navigational aids has been developed, and is now widely used, which, though not actually working on the radar principle, may conveniently be mentioned in this section. In these systems the aim is to produce, in one way or another, a radio "pattern" over a wide area, so that the ship or aircraft can, by observation of the radio signals, tell at which point in the "pattern" it lies, and so fix its position upon a chart or map. As an example of this class of radio navigational device we may mention the "Decca Navigator," an apparatus by means of which the geographical position of a ship or aircraft may be found instantaneously at any time. The system here is for several synchronised transmitting stations on shore continuously to emit unmodulated waves, which, because of the interaction between the waves from the separate stations, produce a "space pattern" over the adjacent land and sea territory which is recognisable by instrumental means. Thus the waves from two such stations can be made to interact, so as to produce a series of maxima and minima, which take the form of curved "lanes"

cated by the second, and then looks for the two correspondingly numbered lines in the two criss-crossing patterns on the chart. The point of intersection of these two lines is the ship's position. It will be appreciated that the above is a simplified description of the working of this system, and that various details have been omitted. It is easy to see, however, that such a continuously recording navigational aid is of great use in ships and aircraft, especially under conditions of fog or darkness, for it enables the position to be ascertained at any time with considerable accuracy, and independently of the ability to observe the usual navigational aids, such as lights, buoys, the sun, or the stars.

Other systems use synchronised transmitters from which pulses are sent out, and the receiver on the ship or aircraft is used to measure the transit times of the pulses from the different transmitters in the group. The measurement is done on a cathode-ray tube, and the position of the pulses on the tube trace indicates the position in a criss-crossing pattern of lines on a chart, similar to that just described.

It will be seen, therefore, that a ship fitted with radar by means of which it is able to "see" the main features of the surrounding territory, with the addition of an aid like the Decca Navigator by means of which its position is accurately indicated at any time, is able to navigate through darkness and fog with almost the same security as would ordinarily apply under conditions of clear visibility. Thus has radio, apart entirely from its value as a means of communication, continued to prove a boon to the seaman and the airman.

## INTRODUCTION.

THIS section has been written with an entirely practical purpose: for it is going to deal with the problem of how you or I, the man, or woman, in the street can be happy and make the most of our opportunities in this exciting, fascinating, but often perplexing and terrifying world in which we live.

Of course, it would be impossible to deal with every special human problem in the space available here. Nor is it desirable to do so; for most problems cannot be solved merely by reading about them. The section attempts to do two things: first, to give understanding (which is the first step in solving any problem) and, second, to suggest where you may go for more personal and detailed advice.

There are also suggestions in this Family Affairs section for those who may require advice on personal problems and marriage and home problems, and some of the principal organisations offering such help are listed at the end of Part I; a list of useful books and pamphlets is also given. Advice is also offered to those who are thinking of buying a house; and there is a guide on the whole field of insurance, both on life and property. It would indeed be a tragedy if you should be needlessly worried or unhappy when there are so many people willing to help. Let us see what can be done!

## I. HUMAN RELATIONS

*By a Doctor*

In most countries scientific knowledge has made possible greater material well-being, better education, better health, and a higher standard of living for the ordinary man and woman, yet it is doubtful whether our capacity for happiness and peace of mind has correspondingly increased. There is an old saying, "happiness is with people," which means that satisfaction in living springs from good relationship with our fellows. This is something which wealth, health, and good education cannot guarantee, no matter how important these things are in themselves.

### CAUSES OF UNHAPPINESS.

If you were a doctor, a social worker, or a psychologist, you would soon find that there are three immediate causes of unhappiness: ignorance, environmental problems, and psychological problems. Most unhappy people are suffering from a mixture of all three.

By *ignorance* I mean that many people are discontented or troubled either because they do not know where to turn for help when it is needed or because they have got into difficulties through not knowing the rules of living.

By *environmental problems* I mean not getting on with the people one has to associate with, being in a job which one finds unsatisfying, and all the other everyday situations which arise from clashes between the individual and his surroundings.

*Psychological problems* are difficult to define; but, generally speaking, I shall speak of "environmental problems" when I mean that the trouble lies mainly in the person's surroundings and circumstances, and of "psychological problems" when I mean that the trouble lies mainly within the individual himself. If, for example, a man is unhappy in a particular job, leaves it, and later finds a job in which he is quite satisfied, we should suppose that it was originally a case of "right man, wrong job"; but if he goes from one job to another, never finding the "right" one, then there is surely something wrong with the man. Similarly, it is quite possible for a girl to meet the wrong man once, or even twice, but if all her attachments end unhappily, it is likely there is something wrong within herself.

### EVERY PERSONAL PROBLEM IS ALSO A SOCIAL PROBLEM.

This means that most of our problems, no matter how personal they may seem, are connected with the type of society in which we live. How to bring up children, what to do with old people, whether a married woman should go to work or stay at home, problems of loneliness, of the unmarried woman, of sex, and even of religion, are problems of people living in a particular society

at a particular time and place. If you are living in present-day Britain, some of these matters are bound to affect you. But if you are living as a small farmer in the South of France or Italy or Greece—or even in the West of Ireland or the North of Scotland—they may hardly have begun to affect you at all. In Central Africa, parts of Asia, or of South America, you could not even conceive of them. Why should this be so?

**Peasant Communities.**—First of all, those areas—rural France, Britain, Italy, Greece, and much of Asia, Africa, and South America—which we choose to think of as relatively "backward," are, in fact, leading the sort of life which was the rule almost the whole world over prior to about 1750. That is to say, they are areas where people make a living on the land, dwell in villages or small towns, and are guided in their conduct by tradition. Peasants living this sort of life have large families, and you would probably find numerous children, the parents, and the grandparents living under the one roof. There are no financial problems relating to children and grandparents, because both are economic assets: from a very early age the children can work with their parents in the fields, and the grandparents stay at home and look after the very young ones. Nor do problems of how to bring up children arise, because tradition ensures that all children are brought up (rightly or wrongly) in the same way. For the same reason, there are few difficulties about sex or religion or moral conduct generally; most people have the same religion (in Southern Europe, the Roman Catholic Church) and the same rules are accepted by everyone. Women work in the fields or at home, and no question of the type—career or family?—can arise, because the choice does not even exist. Nor is it possible to be lonely in such circumstances—in the village or small town everyone is acquainted with everyone else, and whether their feelings are of liking, disliking, or indifference towards any one person, at least they are never unknown to each other. In peasant society there is little room for romantic love, and the plain woman has just as good a chance of marrying as the good-looking one. There is no need to struggle against one's fellow-men, because few people move up, or down, the social scale, and what one is born, one remains. Man's main fight is against Nature, against disease, hunger, and the weather.

**Industrial Communities.**—With the arrival of industrialism all this changes. Great cities arise in which a man does not even know his next-door neighbour; children are unable to work until they are fourteen or fifteen years old; old people and young children are a financial liability, so families become smaller, and the old a problem. People find that the traditional ways of behaving are not

always appropriate to changed circumstances, so tradition disintegrates, and under the impact of science the new ideas that take its place are constantly changing. Instead of the old certainty, there arise new theories about how to bring up children, new beliefs about sexual conduct, marriage, and divorce. Competition becomes the rule, and, instead of remaining in the position to which he was born, a man feels he must strive to outdo his neighbours—to get more money, a better social position. Advertising makes people imagine that they need things they had never thought of, and, although wealth increases, so does frustration. The man whose great-grandparents used to feel frustrated through lack of food feels frustrated because he is unable to buy a radio or television set like his neighbour. (For people are frustrated, not in absolute terms, but in terms of what they actually have and what they have learned to feel they are entitled to.)

**The New Position of Women.**—The First World War brought women into industry to replace the men who had gone to fight, and once they had acquired the taste, they were less satisfied with life at home. Earlier wars had always been small affairs fought by professional soldiers, but from 1914 onwards the rule was total mobilisation of the larger part of the male population, which meant that women *had* to replace the men. This had a number of effects upon the attitude of women. For example, it was now possible for a woman to become economically independent and therefore to divorce an unwanted husband, whereas in Victorian England and in all earlier periods a woman had to put up with a bad husband because he was her only means of support. Also, there arose in the mind of the average woman the conflict—career or family?—which had never arisen before. The new situation meant that the married woman in her less happy moments could look back and say: "What might I not have been if I had continued in business?" Whereas the unmarried business woman could wonder: "How happy I might have been had I married and had children?"

### THE MEANING OF HAPPINESS.

**Pleasure and Happiness.**—Many people confuse two quite different things—pleasure and happiness. *Pleasure* is always temporary and usually physical in origin, and is associated with those things which one usually (depending, of course, upon one's tastes) considers "fun" to do: having a good meal, making love, lying in the sun, listening to music. You will notice that all these things have this in common: (1) they all come through the senses of sight, feeling, hearing, and tasting or smelling; (2) they are always temporary; (3) they are all "pleasant" in the sense that they are, quite simply, enjoyable in the most obvious way. But *happiness* is something quite different; for while it is true that all people enjoying pleasure are, for the time being, happy, the reverse is not true. One can be happy when quite unpleasant things are happening. Let me give you an example. During the War I met three middle-aged ladies who were in charge of a first-aid station—they had never done any job before, because each had been looking after old and infirm parents. At the first-aid station they had to work hard, they were exhausted by the end of the day, they saw unpleasant sights, and they had a lot of responsibility they had never had before, but each of them was happier than she had ever been in her life. Why? *Just because* she was working to some purpose (that is, had an aim in life); *just because* she had responsibility; and *just because* she was doing something which was appreciated by others. "Happiness," said a famous psychologist, "is a state of going somewhere." It is no coincidence that the suicide rate always drops in war-time; for war, in spite of all its horrors, supplies the three emotional needs felt by all normal people—the need to be appreciated—to "belong" as the Americans say; the need to be useful; the need to have an aim in life. There is a dramatic relationship between human misery and loneliness or lack of an aim in life.

**Conclusions.**—In order to be happy one needs a goal to strive for, the love of a few, and the respect of those who share our views. The opinions of others need not matter. Therefore one is unhappy:—

- (1) If one has no goal.
- (2) If one is prevented by circumstances from attaining reasonable goals.
- (3) If one has chosen unreasonable goals which cannot be attained.
- (4) If one is compelled by circumstances to mix with the kind of people one finds uncongenial.
- (5) If one is prevented by one's own personal defects (shyness for example) from mixing with those who are congenial.

There may be three causes of all these five: ignorance, environmental maladjustment, and psychological maladjustment, as has been explained on an earlier page. The second and fourth, for example, are likely to be due to environment, the other three are more likely to be psychological in origin.

### IGNORANCE.

You might be surprised if you knew how many people are miserable through sheer lack of knowledge. Let me give you some examples of what I mean:

**Unnecessary Loneliness.**—Here is Mary, a cheerful, friendly, but rather shy girl who comes to London to get work. Soon she finds herself lonely and quite at sea. The other girls she meets are not the types she can get on with—they are mostly interested in cinemas, parties, sport, and dancing, while she is interested in books and music. Of course, it is easy to say that Mary can, in London, go to as many concerts as she likes, but being shy, she does not like to go by herself, nor has she much money. Yet if Mary would only look up the small advertisements at the back (for example) of the weekly journal *The New Statesman* or *The Spectator*, or at the notices in her public library, she would find that there are many societies catering for people with all sorts of interests—musical societies, political, religious, art, chess, philosophical, and so on, all of which would be only too glad to welcome her. (There is a Guide to Societies on pp. 147–48.)

**Unnecessary Frustration.**—Then there are many men and women who want to do something to help others and feel frustrated in a job which pays good wages but is not really interesting. They would have liked to train as psychologists, social workers, or something "really useful," but find that they are too old to begin, or cannot afford the training, or have inadequate educational requirements. But there are many bodies who urgently need people to do work of this type in their spare time: prison visiting, voluntary work in psychiatric clubs or with the National Association of Mental Health, the St. John's Ambulance, the Red Cross, the W.V.S., amongst others. Many people find that spare-time work of this sort changes their whole life and is capable of giving them a sense of fulfilment.

**Unnecessary Fears.**—Even more tragic are those who suffer from medical or legal problems which could be solved in many cases in a matter of a few minutes by going to the right authorities. Sometimes fear keeps people from consulting a doctor. But uncertainty nearly always causes more misery than knowing the worst—and the worst is not always so bad. Some women, being childless, make themselves (and their husbands) desperately miserable, not realising that there are clinics which deal specially with this problem and can cure infertility. If the infertility cannot be removed, there are the Adoption Societies, who can advise about adopting a child. Many women again who are afraid of having more children either do not know or are too embarrassed to seek aid at a birth-control clinic. Much the same is true of intimate sexual problems, a matter which

will be briefly discussed later. (There is Guide to Organizations prepared to help you on p. 932.) Legal problems concerning housing, hire-purchase, relationships between landlord and tenant, divorce, separation, maintenance often impose a great strain. These, too, can be dealt with when one knows the sources to which one may apply for aid.

**Starting Afresh.**—Lastly, there are those unfortunate people who may have done some wrong at some time in the past, and cannot stop thinking about it. The thought of the evil they have done distorts and spoils their whole life. To such I would like to quote from a great writer: "To have sinned or not to have sinned—what does it profit us in Heaven? In the time I am brooding on my sins, I could have been stringing pearls for the joy of Heaven. That is why it is written: 'Depart from evil and do good'—turn wholly from evil, stop thinking about it, and do good. You have done wrong? Then balance it by doing right." Everyone has made mistakes, everyone has done wrong—but if you go on brooding over it and let it interfere with your duties of today, you are doing much more wrong. (And, besides, you are being intolerably conceited if you seriously think you are much better—or worse—than your other fellow human beings.)

### ENVIRONMENTAL PROBLEMS.

**Difference between Problems of Environment and of Psychology.**—We have already seen that the difference between environmental and psychological problems lies in the fact that in the first case the person's surroundings or circumstances really are difficult; whereas in the second we can see that he has largely created the problems for himself by the way he looks at, or interprets, his surroundings, and, of course, by the way he responds to them.

**No Problem is Entirely Environmental.**—Although the distinction we have made is a useful one, no problem is entirely environmental, for the result always depends upon how the individual sees his situation, and what he does about it. It is "natural" to be unhappy in prison, but some people have been happy there; it is "natural" to be unhappy when one suffers from incurable disease, but, in fact, a large number of people with incurable disease find happiness and more peace of mind than those who are not sick. No, strictly speaking, there are no purely environmental problems—all your troubles are confined in a small area—your head. However, it is useful to make the distinction for practical reasons, for if you are trying to help an unhappy person, the first practical question to ask is: "Can I help him, or her, by getting him a new job, a new home, or new friends, or would he be miserable almost anywhere?" Of course, many people in trouble want to believe it is all the fault of others, of circumstances, of fate (in fact, the more it is their own fault, the more they like to believe otherwise). Some women, for example, assert that all their problems are due to the kind of house they live in, and five or six houses later they are still miserable. Some men are never able to find a "good" job, even after trying dozens. There are men and women who are always complaining of ill-health but who would be desolated if some doctor were cruel enough to remove their only hobby—their real or imaginary illness and their absorbing interest in it. Although we may agree that all troubles are in the mind, it is necessary to distinguish between those that can be cured by a change of surroundings and those which require a change of oneself. The two overlap quite considerably. So, under the heading of "environmental problems," I am going to discuss such everyday matters as bringing up children, marriage, the problems of old people, and some general rules for leading a happy and useful life. You will have to decide for yourself where your own problem lies: are you an ordinary person in unhappy circumstances, or an unhappy person in ordinary circumstances? If you are seriously troubled, it would be a good idea to go to one of the bodies listed at the end of this section (p. 932).

Misery is not conducive to clear thinking, and it is always advisable to get the advice of others, particularly when they are experts in such problems.

**Childhood.**—Psychologists believe (and most sensible people have known for centuries) that the really significant time in life from the point of view of character building is the first five years. That is why it is so important for a child to have a proper start, as reflected in its early training. Some parents fuss and worry over their children in the late teens, when the fact is that if a child is not able to look after itself by that age, the parents must have made a sorry mess of their job. Detailed rules cannot be given about a subject such as this. It would almost be true to say: "It's not what you do—it's the way that you do it." The only fundamental rule—and, of course, I am talking here about the child's character, not its bodily health—is complete, unconditional, and unpossessive love on the part of the parent. If you cannot give this, then all the rules in textbooks are of no avail.

**The Spoilt Child and the Neglected Child.**—There are two kinds of children who grow up into problem people: the neglected child and the spoilt child. The neglected child has had too little love, the spoilt child has had too much of the wrong kind of "love," possessive love, which is not love at all. Here are two examples to show you what I mean:

The first home consisted of father and mother and two daughters. To look at it, you would have said: "What a devoted family." There was nothing the parents would not have done for their children (except to allow them to develop freely). The children were never punished (at least, not physically—but the sorrowing look on the mother's face when they did "wrong" soon brought the children guiltily to heel). Everything the children did was regulated, and now one child at the age of thirty has a nervous breakdown, the other is an old maid at thirty-three.

The second home was a wealthy one, and here, too, there was nothing the parents would not do—at least nothing that money could buy. But the son and daughter were brought up by servants, and the only time they were seen by their parents was in the evening, when they were paraded, in their best clothes, before the adoring father and mother. The daughter, today, has been divorced three times, the son can only manage to live on the money he is continually sponging from others, and the parents cannot understand how all their labours can be so ill rewarded.

**Children Learn by What You Do.**—Children do not learn by what you say, but by what you do. The children in the family first mentioned were spoilt, and, so far from being encouraged to grow up, were encouraged to feel: "All our desire for independence is wrong; we mustn't hurt Mummy's feelings." As adults both children still feel that mother and father want them to stay at home, as indeed they do. The possessive love of the parents had caused the one daughter to remain unmarried, the other, who wanted to get married, and was afraid to hurt her mother's feelings, developed a conflict which made her ill. Perhaps you may say about the second case: "Well, at least I'm not that kind of parent, because I have no servants and I am not wealthy." Perhaps you are not wealthy, but what about the mother who goes back to work when her child is a few months old? The results are just the same.

**Unconditional Love and Consistency.**—Two things are necessary in order to rear happy children: unconditional love and consistency. Unconditional love means that, whether the child does right or wrong, it can feel that the parent's love is always there, that however much one dislikes the deed, one never ceases to love the child. Consistency means that there should not be too many rules, but the rules, once made, should in all circumstances be maintained. If

you make too many rules, the child will lack character, since it is never free to choose and make its own mistakes; if there are too few, the child feels insecure because it never knows "what's what." In short, children should be as free as they are fit to be at any given age. The whole aim of a good upbringing is not that the father and mother should try to coerce their offspring according to their own parental ideals, but rather that father and mother should protect the children while they are growing into their true selves. After all, few people are such big successes in life that they are entitled to force their children into their own mould.

**Mental Cruelty.**—Most people in this country are, quite rightly, sensitive to the problem of cruelty to children—that is to say, obvious physical cruelty. But I doubt whether they are equally sensitive to the problem of mental cruelty. Take the example of the little girl or boy of three or four years old who is allowed to feel neglected upon the arrival of a new baby. Previously he has been in the centre of the picture, yet now he is suddenly left out of it, and assuredly his future happiness will not be helped thereby. Or the mother who would be shocked by the idea of hitting her child, but punishes it by saying: "Mother doesn't love you any more." "All right, go away, we don't care." Or the mother who said that she could always bring her little boy to heel by taking away his best-loved toy when he misbehaved. Or the mother who is always taking her child to a doctor at every slight ache or pain, and in front of the child tells the doctor: "Oh, doctor, I'm so afraid, his father had pains just like that and had to have a serious operation. He's never been the same since." Is this boy likely to grow up feeling a sense of security and having the courage to face life? What do children feel when the two people upon whom their whole security depends quarrel violently in front of them, or when they are always being left under the care of others while the parents go out? No, cruelty is not always physical, and I would even go so far as to say that the most devastating type of cruelty in its effect upon the child is the type of mental cruelty we have just been describing.

**Child Guidance Clinics.**—The infant is primitive, born without morals and only gradually comes to share the grown-up's views on sex, cleanliness, and affection. If you get worried at such things as dirtiness or absence of shame you are revealing more about your own lack of emotional balance than about the child's naughtiness. There is a famous, and very true, saying, "There are no problem children, only problem parents," so if your child is a problem, ask first what mistakes you have made and remember that all psychological difficulties in childhood are due to lack of emotional security. When you notice such signs, take the child to a doctor and ask him to arrange an appointment at the local Child Guidance Clinic. Fortunately, the problems of children are much more easily dealt with than those of adult life. Danger signals which indicate that something should be done are: when the child is more noisy, aggressive, or destructive than the ordinary child; when it is too silent and unwilling to associate with other children; thumbsucking; bed-wetting; nightmares or crying or screaming at night; frequent complaints of pain or sickness when your family doctor can find nothing organically wrong. Remember, the Child Guidance Clinics are there for the purpose of helping you, so there is no need to be hesitant in asking for their aid.

**Marriage.**—Most people nowadays seem to suppose that the only basis of a happy marriage is romantic love. Till fairly recent times marriage was as much to do with parents as with the bride and bridegroom and was regarded as a career for the woman—a career to be carefully prepared for by sex-instruction, and a training in cookery, child-management, and the running of a house. Today many girls rush into marriage from their work in a factory or office knowing considerably less about

running a home, mending, or cooking than the man they marry, who may have been looking after himself for some years. Both men and women frequently share the most childish "romantic" notions, perhaps based upon the films they have seen. They seem to suppose that pleasure, rather than happiness, is the aim of life; that romantic love must last for ever; that marriage is the goal of life (whereas it is only the beginning of learning to adapt to a new way of life); that children are nice but a nuisance; that one's wife, or husband, should remain beautiful or handsome. And, of course, when one is disappointed, there is the final delusion: that divorce is always a solution.

**The Complaints of a Man.**—When this stage is reached, the man will tell the psychologist or the lawyer or the family doctor: "Before we were married my wife used to look so attractive, now she pays no attention to her appearance; she doesn't care properly for our children, and went back to work six months after the last one was born—she was always grumbling about how dull it was being at home all day. Once she liked making love, now she makes all sorts of excuses."

**The Complaints of a Woman.**—The wife's story is the other side of the same picture. "I didn't know marriage would be like this, sitting about all day at home with no friends to talk to. I like my children, but they tie you to the house, and the neighbours complain of the noise they make. So why shouldn't I work? My husband doesn't make enough money, and anyhow I want to meet people. In the evenings he either wants to stay at home or else goes out alone and leaves me to look after the children. Maybe I don't like making love—I'm terrified of having more children."

**Some General Points about Marriage.**—Reading about problems is useful because it can show what is wrong and can give some degree of understanding. But full understanding comes only from experience and personal contact with others. So the points I want to make about marriage must be made quite briefly: First, you will notice in the typical case described above how many of the aspects are social problems peculiar to our times. Second, you will notice an illustration of what has already been said about frustration—that one is always frustrated in terms of what one expects and does not get, not at all in terms of objective reality. In other words, if you expect too much, or if you expect different things from what you are going to get, you are bound to be disappointed no matter how "lucky" you appear to other people. It is not always life or "fate" that is to blame for human misery; very often it is the way the individual looks at life and his unrealistic demands upon it that causes the trouble. This point is so important, and so little understood, that it is worth while saying something more about it. When one says that every personal problem is also a social problem, what is meant is that the kind of problem we have to face is partly created by the society in which we live. It does not mean that we are the helpless playthings of fate; for the way in which we deal with the problems is very largely our own responsibility.

Divorce is sometimes the only solution to a marriage which has failed, but there are two dangerous things about divorce which should be taken into consideration. First, the fact that divorce is possible makes people think of it as the obvious answer when trouble arises instead of trying to do something when a marriage could still be saved. Second, just because failure in marriage is always due to the personal defects of both people, unless these defects are remedied the second marriages will be no better than the first. Divorce, as any doctor or lawyer could tell you, is often a case of "out of the frying-pan into the fire," when the individuals concerned remarry. One woman I knew married no less than three times—and each time "happened" (because of "fate" she said) to marry a drunkard. Of course, the only element of fate involved was within herself, the defect in her own personality which made her choose a certain type of man.

**Steps to Happy Marriage.**—I could have occupied some space in this section telling you about the sort of behaviour which leads to a happy marriage: a spirit of give and take, tolerance, and so on. But, unfortunately, people either have these qualities or they do not, and you certainly cannot obtain them by reading about them. So, if your marriage is in serious difficulties, the proper thing to do is to go to a Marriage Guidance Clinic for help. However, here are some aspects which you can do something about, and most doctors and psychologists would agree with the following points:—

(1) Before marriage a woman should learn something about running a house, cooking, and bringing up children.

(2) Reflect upon the meaning of love. Although "love" is a word which is often talked about rather glibly, it can have a number of different meanings. *Romantic love* is based upon sentiment (often upon sentimentality), and its essential feature is an idealisation of the other person, so that one all too often sees in the beloved qualities which are not there. That may be a good thing, but it is certainly no guarantee in itself of a happy marriage as the divorce courts make painfully clear. Reflect carefully upon the nature of *possessive love*, based upon a desire to possess the other person regardless of his or her own best interests. One thinks here of the mother or father who unwittingly prevents children who have grown up from leading their own lives, or of the jealous wife or husband who will not let his or her partner in marriage go out or meet other people. Possessive love is not really love at all. True love is based upon mutual respect and a deep desire to further the other person's best interests whatever sacrifice one has to make oneself. A famous French writer said this of possessive love:—"If (possessive) love is judged by its effects, it resembles hate more than friendship." If your "love" leads to bad results, whether in your husband, wife, or child, you had better look within yourself for the reason why.

(3) Keep your good appearance. Both husband and wife should keep up appearances after marriage just as they did before; they should not, in other words, let themselves "go to seed" in the home, lose their good manners, or dress carelessly, with the implied attitude that it no longer matters what the other partner thinks. In this sense marriage should be an eternal courtship in which one always goes on trying to please the other. True, this will not save a basically impossible situation, but lack of the observance of this rule may break up a marriage which well might have been saved.

(4) Lastly, two observations about children. First, a couple should never have a child with the sole intention of trying to prevent a marriage from going on the rocks. It is unfair to the child, and if a marriage is in such a bad way, having a child is unlikely to have the desired effect. Second (and this may be an unpopular statement), *every child needs the full care of its mother in the first five years of its life*. One of the reasons for the increase in juvenile delinquency in recent years is the failure of mothers to give the child full attention. The family has been called "the character factory of society," and character is formed in the first five years of life; without the mother the factory cannot work properly.

**Sex.**—It is often said that more marriages break down because of sexual difficulties than for any other single reason. As it stands, this statement is not true. Sexual difficulties come into two categories: those due purely to ignorance, and those basically due to *personality* problems between the two partners. The first kind are a straightforward medical matter, which can be solved by a family doctor, by a Marriage Guidance Clinic, or even by reading a good book on sex technique. The other kind are an entirely different matter: for here the sexual difficulty does not cause the trouble in the everyday relationship between husband and wife, but their unsatisfactory everyday relationship causes the sexual difficulty. For example, if the wife

suspects infidelity on the part of her husband, if she has had an unhappy home life with her parents which leads her to suspect men or fear sex or marriage, if she is afraid of having more children, or if she feels a latent resentment towards her husband over some matter quite unrelated to sex, these feelings may make her sexually frigid. With women, as contrasted with men, sexual happiness is impossible unless the total personal relationship between the partners is satisfactory. A list of books about sex is given on a later page, but where the problem lies in the sphere of personal relationships the help of a psychiatrist or the Marriage Guidance Clinic must be sought. We must, therefore, reverse the statement that sexual difficulties (except those due to ignorance) cause marriage difficulties; the truth is that difficulties in the everyday relationships between the partners cause sex difficulties.

**Old People.**—We live in a society which has the highest proportion of old people anywhere in the world, and the proportion will go on increasing. Old age is, of course, associated with a decline in physical and mental powers, but social and medical factors may hasten or slow down this decline. For example, the person who has led an active life often rapidly deteriorates when he has to retire or when he lives by himself and is thus cut off from human society; he loses interest, becomes untidy, and does not look after himself properly. He has, in fact, nothing to live for and shows it in his behaviour. In cases like this there is often a dramatic improvement when the old person goes to a Residential Home where he gets proper food and, above all, company and things to do. *A great deal of the appearance of deterioration in old age has to do, not with physical, but psychological factors:* lack of a goal, a feeling of being unwanted, loneliness, and all the things we have already seen to be so important for psychological health and happiness at all ages. The grumpiness, the interfering, the selfishness often associated with old age are largely due to circumstances rather than natural "cussedness"; they are the reactions of anyone who feels unwanted or useless, and many of the so-called problems of the aged would be removed if they were allowed to continue work under suitable conditions. The aged may be cared for:

- (1) in their own home, living alone;
- (2) in the home of their children or relatives;
- (3) in an Old People's Residential Home;
- (4) in the Geriatric Unit (for the sick and aged) of a Hospital.

**Welfare of Old People.**—In 1940 the National Council of Social Service sponsored the formation of the National Old People's Welfare Committee, which now co-ordinates the activities of voluntary organisations, seeks to bring about improvements in legislation, and, in general, studies the needs of the old. Some of the services provided by various bodies, information about which may be obtained from the secretary of the local Old People's Welfare Committee, are: Home Nursing Service, Health Visitor Service, Home Helps, Night Attendance, Physiotherapy, Chiropody, Meals Service (meals brought to the home or arranged in nearby centres or restaurants), extra foods, baths, free laundry service, mending service, coals and logs, and holiday schemes.

**Attitude to the Old.**—Where the aged are cared for depends primarily upon medical factors, which should be discussed with the family doctor. Obviously, a sick person cannot stay by himself at home, but, on the other hand, a healthy person cannot be sent to the Geriatric unit of a hospital. One must think of the other members of the family, and here the moral problems begin: should one look after one's aged relatives even if they are troublesome and a whole-time problem, or should there be a limit set to one's responsibilities in this respect? The answer must be personal, and one suggestion is that the old (and, in particular, our parents) are entitled to expect some attention from their

children. But, on the other hand, nobody is entitled to expect another person to give up his whole life to this end. A parent is fully entitled to expect from son or daughter as much as the parent has done for them, and a parent will accept what son or daughter willingly chooses to do. But a parent must not demand the sacrifice of marriage, career, or happiness. If an unmarried daughter genuinely wishes to look after her father or mother, giving up all hope of any other career, she may, of course, do so; but to give up her whole life *unwillingly* to this end is not being self-sacrificing, but wrong. We have a duty to others, and particularly to our parents; but we also have a duty to ourselves. Such problems should be solved by considering the best interests of all those involved—the greatest happiness of the greatest number—and the younger the individuals concerned, the more consideration they are entitled to. One should help one's parents or parents-in-law, even at considerable sacrifice, but not to the extent of sacrificing the whole of one's life, the happiness of one's marriage or children.

**The Sacred Rule of Non-interference.**—No situation is more liable to cause trouble than the interference of one generation in the affairs of another. In particular, the older generation should never give unasked advice to the younger—especially concerning the upbringing of grandchildren. If your children are not capable of reasonable behaviour once they are adults, they are certainly not likely to be changed by unwanted advice. Nor should parents interfere in the quarrels of their married children; if any interference is called for, it should come from those who are less emotionally involved.

### PSYCHOLOGICAL PROBLEMS.

We have seen that a psychological problem is one which is caused less by your surroundings than by the way you look at them. You should suspect that your problems are primarily psychological: (1) if the same situation in life keeps cropping up—love affairs always ending unhappily, jobs always being lost or given up, and so on; (2) if you have difficulty in getting on with your fellows; (3) if you are depressed, anxious, or unhappy without obvious reason; (4) if you have nervous symptoms, *e.g.*, irrational fears (of closed spaces, open spaces, or disease), sudden attacks of panic or anxiety, or pains for which the doctor can find no adequate explanation. These conditions, whether they masquerade as personal problems or as "nerves," have this in common: they are caused by a faulty attitude to life, and, in particular, to other people, originating in early training. "*Nerves, neurosis, and psychological problems in general are not diseases in the ordinary sense, and are always caused by fundamental misunderstandings in the sphere of human relationships.*"

**The "Bad" Emotions.**—Many people have troubles of this sort, and doctors say that 60-70 per cent. of all their patients come into the category of people who are suffering from the "bad" emotions of hate, anger, resentment, fear, and anxiety—people who are ruining their own lives because of the past. Some of them create their own problems in everyday life, others suffer from "nerves," and yet others develop those physical illnesses due to prolonged worry and emotional stress: stomach ulcer, "fibrositis," high blood-pressure, heart trouble of certain types, headaches, some kinds of skin disease, and so on.

**Needless Distress.**—Most of us have such problems from time to time, and sooner or later they pass, but when such problems are persistent it is necessary to consult a psychiatrist. True, in most cases such states are not dangerous—men and women with "nerves" do not (as so many of them fear) go insane. But they suffer a lot of needless misery. If you are suffering from any of the problems mentioned above it would be a good idea to ask for expert advice at one of the bodies mentioned below.

**Some General Advice.**—Here is some advice, collected from widely different sources, dealing with the rules of happy living:—

(1) *Don't Worry.*—Worry is a waste of time; it is also dangerous. Try not to worry about either the dead past or the unborn future. Sir William Osler, one of the greatest doctors who ever lived, said this: "Shut off the past! Let the dead past bury its dead! The load of tomorrow, added to that of yesterday, carried today, makes the strongest falter. Shut off the future as tightly as the past—the future is today—there is no tomorrow. The day of man's salvation is now. Waste of energy, mental distress, nervous worries dog the steps of the man who is anxious about the future." Much the same advice was given in the New Testament: "Take therefore no thought for the morrow; for the morrow shall take thought for the things of itself. Sufficient unto the day is the evil thereof." Note that the words "take no thought" do not mean "make no plans"; in Biblical language they mean "don't worry" about the future.

(2) *Work Well.*—The best cure for worry is hard work. Bernard Shaw wrote: "The secret of being miserable is to have the leisure to bother about whether you are happy or not."

(3) *Have Good Aims.*—"Happiness is a state of going somewhere"; have an aim in life. Cultivate friends and concern yourself with other people's well-being rather than exclusively with your own. Happiness is a by-product of leading a useful life and cannot be found by a deliberate search for it. "Whoever will save his life shall lose it."

(4) *Help Others.*—Try to help others whenever possible, but do so from the inner joy of giving and helping, not in order to earn their gratitude. Gratitude is one of the rarer virtues.

(5) *Don't Expect too much from Others.*—Don't be cynical about people, but, on the other hand, don't expect too much of them. Marcus Aurelius, the Roman emperor wrote: "I am going to meet people today who talk too much, people who are selfish, egotistic, ungrateful. But I shall not allow myself to be surprised or disturbed, for it would be impossible to imagine a world without such people."

(6) *Be Modest in Your Demands of Life.*—Don't expect too much of life, and certainly don't allow yourself to feel permanently frustrated if you fail to get what you want. The Roman philosopher Seneca said: "If you have what seems to you to be insufficient, then you will be miserable even if you possess the world."

(7) *Avoid the "Bad" Emotions.*—Avoid like the plague the harmful emotions of anxiety, fear, hate, resentment, and jealousy. They are a waste of energy; they make you an unpleasant companion to others; and they may make you seriously ill. The resentful and jealous or aggrieved person is, as Shaw puts it: "a self-centred little clod of ailments and grievances complaining that the world will not devote itself to making him happy."

(8) *The Character of Our Own Thoughts.*—In the last analysis all troubles are psychological—they are never entirely determined by circumstances. "Our life is what our thoughts make it," said Marcus Aurelius.

(9) *The Selfishness of Depression.*—Nearly all depression is a form of selfishness. Alfred Adler the psychologist wrote: "It is the individual who is not interested in his fellow men who has the greatest difficulties in life and does the greatest injury to others. It is from among such individuals that human failures spring."

(10) *Cultivate Your Religion.*—Dr. A. A. Brill, a leading psycho-analyst, has said, "anyone who is truly religious does not develop a neurosis," and the greatest living psychiatrist, Professor C. G. Jung wrote: "Among all my patients over thirty-five there has not been one whose problem in the last resort was not that of finding a religious outlook on life. Every one of them fell ill (with neurosis) because he had lost that which the living religions of every age have given to their followers, and none of them has been really cured who did not regain his religious outlook."

## WHERE TO OBTAIN HELP ON PERSONAL PROBLEMS AND ON MARRIAGE AND HOME PROBLEMS.

The following are some of the principal organisations:—

**Marriage Guidance Councils**, 78 Duke St., Grosvenor Sq., London, W.1 (Mayfair 2731-2).—Marriage Guidance Councils are at work throughout the country; and headquarters at the above address will gladly give the address of any of these local Councils. The Scottish Marriage Guidance Council at 44 Queen St., Edinburgh, co-ordinates the Councils in Scotland.

The Councils offer skilled, kindly, and confidential help to those who want it before marriage and after. Besides mutual love, the important factors in success in marriage are a happy home background, agreement on fundamentals, loyalty, courage, and humour. People cannot be given a sense of humour, but there are things they should themselves settle in advance of marriage, like religious belief, family intentions, sharing of money, and relations with in-laws.

Particular help is given to engaged couples on all aspects of marriage and parenthood. This is done by private consultation and by informal discussions for small groups of engaged couples.

After marriage, Marriage Counsellors—men and women volunteers most carefully selected and trained for the task—offer help in all aspects of marriage to those who seek it.

The Council issue a list of recommended books and pamphlets, which are normally available at the Council's Book Room for inspection. Books can be despatched by post in plain wrappers. Some of these books and pamphlets are referred to in the list given in this section.

**The National Association for Mental Health**, 39 Queen Anne St., London, W.1 (Welbeck 1272).—This voluntary body provides an advisory service for individual cases. It can help you to understand your children's problems; or (if you are a teacher) it can help with courses about the development of children and their intellectual capacities). If you have the care of old people it can help you to make the best arrangements for their care; and if you have a backward child it can help you about schools and special centres. If you have a personal problem the Association can put you in touch with good advisers. It will help you to find the nearest Psychiatric Out Patients Clinic or Child Guidance Clinic. You may want to help mentally handicapped people, and if so the Association can advise you about training and can offer courses to qualify you for work with backward children.

There are 20 voluntary Mental Health and Mental Welfare Associations under the aegis of this National Association throughout the country.

**Family Planning Association** (1930), 64 Sloane St., S.W.1 (Sloane 0451).—*Objects:* (a) To advocate and promote scientific contraception so that married people may space or limit their families. (b) To advocate and promote the establishment of Family Planning Centres, at which, in addition to advice on scientific contraception, advice and, where necessary, treatment are given for any or all of the following—(i) involuntary sterility; (ii) difficulties connected with the marriage relationship. (c) To encourage the production of healthy children who are an asset to the nation, provided that their parents have the health and means to give them a reasonable chance in life. (d) To examine such other problems as are relevant to the above, and to take such action as may be considered advisable.

The F.P.A. has 200 clinics throughout the country, many on local authority and hospital premises, and a sub-fertility investigation unit and postal advice department and pregnancy diagnosis service at its Headquarters. The Association is supported by voluntary funds, and the clinics' fees are modest; no one is refused advice because of inability to pay.

**Family Welfare Association**, Denison House, 296 Vauxhall Bridge Rd., London, S.W.1 (Victoria 733418). The National Assistance, National Insurance,

and National Health Service Acts have assured to the citizen the satisfaction of many basic needs, but many people still require certain forms of personal service which the State does not provide. It is here that the Family Welfare Association has its place.

The Casework Service of the Association is carried out in local offices, of which a list can be obtained. Many family difficulties can be resolved by comparatively simple forms of help. In addition to providing a casework service, the Association, in its local offices, gives practical training to students in family casework.

In addition, the Association sponsors: (1) the Old People's Homes Committee, which gives advice on suitable Homes for elderly people and problems of old age; and, (2) The Family Discussion Bureau, described below.

**The Family Discussion Bureau**, 4 Chandos St., London, W.1 (Langham 7045/6).—The Bureau is a centre serving the London area where people of all ages, married or single, may go and discuss freely difficulties in family relationships. Interviews take place in a quiet informal atmosphere and under conditions of professional confidence. Difficulties of sharing a house or managing children, sexual maladjustments, and other marital anxieties are real enough in themselves, but it is often the personal unhappiness underlying these which make them so impossible to bear. The service is free. Those wishing to consult the Bureau, or to refer to others, are asked to telephone or write. Appointments can usually be arranged within a few days.

**Family Service Unit**, 25 St. Mary's Grove, London, N.1 (Canonbury 6662).—(There are Units also in Islington, Kensington, and Stepney, London; and in Liverpool, Sheffield, Leicester, York, Manchester, Birmingham, and Bristol. For addresses apply to above address.) This organisation provides a voluntary specialised service for "problem families." For this purpose "problem families" does not mean any family in difficulties, but families where conditions have been such as to lead to neglect of children. Sometimes parents are disabled or suffering from chronic illnesses. For the families' own welfare and that of the community they need help. Family Service Units exist to meet this need.

**The National Association for Maternity and Child Welfare**, 5 Tavistock Place, London, W.C.1.—Gives enquirers much useful advice on these matters.

**Maternity and Child Welfare Centres**.—The address of the nearest Centre can be obtained from your doctor, a hospital, or the local council offices. The Local Education Authority provides Nursery Schools for children between two and five.

**Home and School Council of Great Britain**, 81 Endsleigh Gardens, London, W.C.1.—Gives advice on the formation of a Parent-Teacher Association, if there is no such association at a school.

### Other Useful Addresses.

The National Adoption Society, 4 Baker St., W.1.

The National Children Adoption Association, 71 Knightsbridge, S.W.1.

The After Care Association for Physically Handicapped Children, 54 Bloomsbury St., W.C.1.

The National Institute for the Blind, 224 Great Portland St., W.1.

The National Institute for the Deaf, 105 Gower St., W.C.1.

### SOME USEFUL BOOKS AND PAMPHLETS.

For Married or Engaged Couples.

*The Art of Marriage*, Dr. Mary Macaulay (Dellisle, 7s. 6d.).

*The Sexual Side of Marriage*, Dr. M. J. Exner (Guild Books, 2s.).

*The Sex Factor in Marriage*, Dr. Helena Wright (Williams & Norgate, 3s.).

*Modern Contraception*, Dr. P. M. Bloom (Dellisle, 2s.).

**Childbirth and Baby Care.**

- Fearless Childbirth*, Minnie Randall (Churchill, 3s. 6d.).  
*The Nursery Years*, Dr. Susan Isaacs (Routledge, 2s. 6d.).

**Marriage Problems.**

- Any Wife of Any Husband*, Medica (Heinemann, 10s.).  
*The Change of Life and its Problems*, Dr. L. B. Jeffries (Gollancz, 4s. 6d.).

**Young People.**

- Grow Up and Live*, Dr. Eustace Chessier (Penguin, 2s. 6d.).

**Parents.**

- The Intelligent Parents' Manual*, F. Powdermaker and L. Grimes (Penguin, 2s. 6d.).  
*You and Your Children*, Dr. Doris Odum (H.M.S.O., 9d.).

**The Home.**

- Your Home and You: The Homemaker's Encyclopaedia*, Kay Smallshaw (Peter Nevill, 21s.).

**Women.**

- The Art of Being a Woman*, Amabel Williams Ellis (Bodley Head).

**Everyone.**

- How to Stop Worrying and Start Living*, Dale Carnegie (Pocket Book Inc.) (published in America but available in the U.K.).

**Retirement.**

- Retire and Enjoy It*, Cecil Chisholm (Phoenix House, Ltd.).  
*How to Retire and Start Living*, Eleanor Brockett (Staples).

## II. HOW TO BUY A HOUSE

### 1. INTRODUCTION.

The following guide has been compiled to help those who want to buy a house, especially young people founding a home. For many of us the need to buy a house comes but once in a lifetime; or, at any rate, so seldom that we have little experience to guide us. Many people, therefore, pick up such knowledge as they can at the last moment as they go along. That they tumble unawares into pitfalls is not therefore surprising. It is to save the house-seeker from those mistakes, which can be so costly and worrying to him, that the following guide is offered.

The guide has two main parts: first, how to make sure that the purchase is a sound one; and second, how to obtain the necessary funds. In addition, there is an explanation of the rates and income tax on a house and what reliefs can be obtained.

The advice may well seem more complicated, at first sight, than the newcomer to the problem expected. But when he reads it the main points will be found to be simple and clear, and the advice will repay careful study.

In addition to an explanation of how to select a house and get the money for it, information is offered on important subsidiary matters, such as how the purchaser may assure his family if he dies before a mortgage is paid in full. It is also explained how grants can be obtained for conversions and improvements.

The figures quoted in this section are those ruling at the time of going to press.

### 2. THE ESSENTIAL QUESTIONS TO ASK.

**The Nature of the Property.**—There are certain preliminary points which you need to get clear before entering into any commitments. You should think most carefully over the general position of the site; the nature of the soil; handiness to shops; what daily transport is available and what schools there are in the neighbourhood. You should ascertain the exact nature of what is being sold. Is the land leasehold or freehold? If it is leasehold, your ownership will be only for a stipulated number of years, often ninety-nine, sometimes more and sometimes much less; rent will be payable; and there are likely to be restrictions on its use. Though freehold usually means outright ownership of the land, freehold may also carry restrictions, such as debarment on use for business purposes or conversion into flats, or there may be limitations on the type of structure or size of house which can be built.

**The Nature of the Neighbourhood.**—Next comes essential information about the neighbourhood as a whole. Is it already zoned, or likely to be zoned, for industrial or other non-residential development? Are developments in hand, or possible, near enough to be inconvenient or liable to affect the amenities or value? The local Planning Authority (whose address you can find

from the local council office) can usually give guidance on all these points. Equally essential is to find out if the land is subject to any rights of way, or other "easements" as they are legally termed.

**Services and Roads.**—Handiness to main drainage and gas, electricity and water supplies must be considered; installation may be costly, if any or all of these services have to be carried some distance. If roads have not been made up or adopted by the council, it should be found out when they will be built or adopted, where they will run, and the probable liability in road charges.

**Local Bye-laws and Planning Clearance.**—Assuming a clear bill up to this stage, local bye-laws and planning rules must be taken into account if a new house is to be built. Not any kind of building can be put up. It must conform to local standards of construction and safety. Its outward appearance and the facing materials used must also be approved by the local Planning Authority. An architect is the best adviser on these points. Once bought or built, owners cannot do anything they wish with houses. In addition to any restrictions going with the land, as mentioned above, the local Council and Planning Authority may have a definite say in all proposals. For example, their approval is necessary before a house can be converted to flats or for business purposes, or put to any other use.

**The Need for a Surveyor and a Solicitor.**—A qualified surveyor should be called in to report on the condition and value of an existing house in which you are seriously interested. You will thereby know exactly what it is you are thinking of buying, and you will know within limits what you ought to pay. Various legal points must also be considered, and a solicitor should be consulted at the earliest stage of negotiation, to look after matters such as the title to the property, restrictions on use, conveyance and, a complicated matter calling for expert advice, the likelihood of the land being lost by compulsory purchase. On written application to the local council it must state whether, so far as it knows, the land is liable to compulsory purchase within five years.

**The Golden Rule**, is therefore: 'Obtain professional advice at the earliest stage—from a surveyor and a solicitor acting for you and independent of another party to the transaction. Where necessary, as, for example, when building a house, you should also consult an architect. The safe rule is not to enter into any commitment of your own bat. But if you do make any undertaking make sure that you introduce into your undertaking the words "subject to contract." Thus if you pay a deposit to a house agent as stakeholder state, in writing, that the payment is "subject to contract."

### 3. HOW TO BUDGET.

**Stamps and Fees.**—Sufficient money must be available to cover every need. You will, of course, remember that expenditure does not stop at the cost of the property itself. You will need to have money for stamp duties, legal charges, and expenses on the conveyance (or transfer) of the house if it is being bought, or on the land only if it is being built to plans; stamp duties, legal and inspection fees, and expenses in connection with the mortgage if money is being borrowed; and a fee for the surveyor who examines before purchase. All are payable by the purchaser. The actual amounts depend on the purchase price of the property or land and the amount of any mortgage advance. Stamp duty, payable to the Inland Revenue, as from August 1, 1956, is 10s. a £100 between £500 and £3,500; £1 per cent. between £3,500 and £4,250; and £1 10s. per cent. over £4,250 but not exceeding £5,000. Legal charges are at a set scale related to the purchase price. For example, if the land is unregistered the scale is 2½ per cent. on the first £1,000, 1½ per cent. on the next £2,000, and ½ per cent. on the next £7,000. If the land is registered at H.M. Land Registry, fees are less, rates being 1½ per cent. on the first £1,000, 1 per cent. on the next £2,000, ½ per cent. on the following £1,000, and so on; but Land Registry fees will be payable at the rate of £3 15s. for the first £1,500 and 2s. 6d. for each extra £50 or part of £50.

**Total Expense for the Conveyance.**—A reasonable estimate of the maximum total expenses for conveyance, including incidental expenses and stamp duties, is, therefore, about 3½ per cent. on the purchase price—less, of course, if the land is registered. Further, though smaller, sums will be payable if a mortgage has to be arranged. The whole set of expenses can add as much as 4–4½ per cent. to the outlay.

**Other Monetary Needs** may include: removal expenses; cost of fittings, curtains, and new carpets; structural alterations, decorating, etc.; new or additional furniture; and laying out a garden, including the cost of tools. The total will depend on circumstances and particularly whether you are moving to a new house or setting up home for the first time. The total amount can be substantial, and it is important that before entering into any commitments, you should draw up a budget of what capital you need; and if insufficient capital is available you should ascertain the amount which can be borrowed on mortgage. How to obtain a mortgage is explained in the next paragraphs.

### 4. HOW TO RAISE A MORTGAGE.

**Who Lends Money?**—Building Societies, Insurance Offices, and Local Authorities all lend money to enable people to own their homes. Banks also lend money and, subject to membership conditions, Trade Unions and Friendly Societies. While details may vary, some broad general rules apply to most methods. They are: (1) The property must be freehold or, if leasehold, must have a life of 20–30 years more than the repayment period of the mortgage. (2) The property must, in many instances, be constructed of brick, stone, or concrete—timber-built or half-timbered houses will not be entertained by some lenders. (3) The loan will be calculated on the value as decided by the lender's surveyor or the purchase price, whichever is the lower. (4) Normally, only a proportion of the price or value will be advanced, the amount usually depending on: (a) the age, condition, size, and situation of the house; (b) the lending policy of the mortgagee; and (c) the age, financial position, prospects, and family circumstances of the borrower. A useful general guide to (c) is that, in order to avoid taking on financial commitments which might become burdensome, mortgage repayments, rates, and a fair allowance for repairs should total not more than around one-quarter of the borrower's income.

**How Much is Lent?**—The percentage advanced varies widely, and depends partly on the method of borrowing. But a broad indication for free-

hold or long leasehold properties for owner-occupation costing not more than, say, £2,500–£3,000 is: new, up to 85 per cent.; reasonably modern older types, up to 75–80 per cent. On higher priced, large or pre-1918 houses the amount may be anything from 50 to 66½ or 75 per cent. Where the price is substantially below current market value, such as may happen if a rent-controlled house is being bought at a favourable figure by a sitting tenant, most lenders will advance a larger proportion; though, on the reasonable stipulation that the owner should have some cash stake in the property, probably not more than 95 per cent. of the cost. Likewise, as explained in later sections, larger loans may be made when suitable guarantees or additional security can be provided.

**Loans for Houses Being Built.**—Special considerations apply when building one's own house. Loans are not normally made on bare land; but if its purchase and commencement of building are a more or less continuous operation, an advance may be made on the land if its value is: (a) high in relation to the total cost of the completed property, and (b) more than the borrower will have to find himself. For example, if the land costs £500, building, etc., £2,000, and a loan of 85 per cent. will be made on the total of £2,500, a sum of £125 would be advanced on the land itself. In every case, however, the amount lent will be based on the surveyor's valuation of the completed property. This will take into account the cost of the land, building, and architect's fees, which latter are properly reflected in the value. It is possible in most cases to have the advance in up to three or four instalments as various stages of building are completed. Whatever the nature of the property, the borrower has to pay out of his own resources the costs of conveyance of the house or land, as mentioned earlier, plus legal and other charges in connection with the mortgage. As explained before, the two sets of expenses can add a further 4–4½ per cent. to the cash outlay.

**Three Points for the Future.**—Make sure when arranging the advance that lump sums can be paid off at any time, with a proportionate reduction in the interest payable. You can ask the Building Society if an extra loan will be possible should money be required at some future date to pay for additions, improvements, or heavy repairs. Finally, if for any reason whatever, it is difficult to keep up repayments, discuss the problem with the lender at the earliest stage—a temporary reduction in payments will probably be made to tide over the difficult period.

### 5. HOW A BUILDING SOCIETY HELPS.

**The Need for Early Consultation.**—Building Societies encourage prospective owners to discuss their propositions with them at the earliest moment. By finding out how much you can borrow you can be saved a lot of disappointment and loss of money by way of deposits and survey fees.

**Surveyor's Inspection.**—Inspection of the property by the society's valuer is the first step after the preliminary discussion. A typical scale of fees is £2 on a purchase price up to £500, with additions of 10s. for every extra £250 up to £2,000 (at which level the fee is thus £5) and 4s. per £100 thereafter up to £10,000; plus travelling expenses over a certain distance. The valuer's report is confidential to the society, and is not available to the applicant. A decision to offer an advance is made normally within a day or two of the receipt of the report. In the case of new houses built to individual design preliminary arrangements and the offer of an advance are made on the basis of architects' plans and builders' estimates.

**How Much Will Be Lent?**—Societies, when a substantial loan is wanted, make the figure as large as possible commensurate with the security offered, the ability of the borrower to meet repayments, and their individual policy. Normal maximum amounts are 80 per cent. on reasonably

modern properties costing up to some £3,500 and 85 per cent. on new ones valued at not more than £2,500. Increased proportions may be arranged, however, if additional security is provided. Up to 95 per cent. may be considered if the borrower himself can provide extra security in the form of Trustee Securities, National Savings Certificates, another property, or a life-assurance policy with a sufficient surrender value. Up to 90-95 per cent. may also be arranged if a third party of financial substance will put up good security to cover part of the loan.

**Guarantee Schemes.**—Building Societies offer guarantee schemes in conjunction with insurance companies. One special plan provides for 95 per cent. advances to approved applicants on properties valued at, or costing, not more than £3,350. A single insurance premium of 7½ per cent. is charged on the amount of the extra loan, the borrower paying half in cash and the other half being added to the mortgage debt—*e.g.*, if the extra loan is £200, half the single premium of £15 is paid at the outset by the borrower. Under another scheme covering maximum advances up to 90 per cent. on a value up to £4,500, the whole of the premium may be added to the loan.

**Methods of Repayment.**—Optional methods of repayment are offered by most Building Societies. The *Monthly Repayment* system is the most widely used and popular. Equal calendar (or lunar) monthly instalments paid throughout the term of the mortgage cover both interest and repayment of principal. Typical calendar monthly payments on each £100 borrowed for various periods and different interest rates are:

Number of Years	Interest Rate		
	5%	5½%	5¾%
	<i>s.</i>	<i>s.</i>	<i>s.</i>
	<i>d.</i>	<i>d.</i>	<i>d.</i>
5	38	38	39
10	21	21	22
15	16	16	16
20	13	13	14
25	11	12	12

While repayments can be arranged over any lesser number of years, the normal maximum is twenty to twenty-five, though some societies may arrange longer terms in particular circumstances. The advantage of this system is the even spread of the outgoings. In the early years the greater part of each payment represents interest, which, however, falls steadily as the loan is reduced. The society usually reserves the right to increase—or reduce—the rate of interest on giving due notice. Increases are applied in ways giving the minimum inconvenience to the borrower, often by extending the repayment period.

## 6. HOW LOCAL COUNCILS AND BANKS HELP.

Local Authorities, including County Councils, can, if they wish, advance money for home ownership under the Small Dwellings Acquisition Acts and the Housing Acts. Applications for details of mortgage facilities available for the area in which the property is situated should be made to the Treasurer or Clerk of the appropriate local Council. These facilities apply only where the value or cost of the property, whichever is the lower, does not exceed £5,000. Interest is generally charged at ½ per cent. above the rate at which the Council itself borrows from the Public Works Loan Board, which fixes its rates in accordance with money-market conditions and the term of repayment. Rates charged to home-buyers at the time of writing (September, 1955) are 4½ per cent. for repayment over not more than five years and 5½ per cent. for longer repayments. The interest cannot be increased or decreased

during the period of the loan. There is, of course, no life-insurance protection; but, as explained in the Life Assurance section, this may be arranged by taking out a reducing term, or mortgage protection, assurance.

Loans can be made under the Housing Act for the conversion of buildings into houses or flats and for the alteration, enlarging, repair or improvement of dwellings. (See paragraphs below on Improvement and Conversions.)

**Bank Loans.**—Banks are sometimes prepared to help within certain limits, the main considerations being that: (1) the borrower is an established customer of good standing; (2) the advance can be reduced steadily and repaid entirely over a relatively short period of, say, eight to ten years at the outside; and (3) no more than two-thirds to three-quarters of the value is to be lent, or additional security such as marketable investments, other property, or life assurances with surrender values can be put up. A bank loan is subject to half yearly or annual renewal, and may therefore have to be repaid on due notice, though this is given only in exceptional circumstances.

**Private Mortgages,** up to two-thirds or three-quarters of the value, may also be obtained, mostly through mortgage brokers, solicitors, and estate agents. Interest may be ½ to 1 per cent. more than on building society advances. Repayment may be by instalments, but is more usually in one sum at the end of an agreed term, which calls for the accumulation of funds. This private field is often the best one for raising a second mortgage when it is impossible to obtain enough in the normal way on a first charge. Second mortgages, in view of the risk involved, generally have to be repaid over a comparatively short period of, say, two to three years and the interest ranges up to 7 or 8 per cent.

**Bridging between One House and Another.**—It may be necessary to bridge a gap between payment for the new house and receipt of the proceeds of sale of the old. If the present house is not mortgaged and no loan, or only a relatively small one, is needed on the new property, the bank may be able to help. If the present house is mortgaged, consult the lender. Arrange the financial side well before entering into any contracts or commitments on the new transaction. Established mortgage brokers and insurance brokers can be of help in the arrangement of mortgages, especially where it is desired to link the loan with endowment or mortgage protection assurance; or it is difficult to obtain the full amount required through the direct channels.

## 7. RATES.

Rates, levied by Local Authorities, are payable on all occupied house property—by the owner if he is also the occupier and often by the tenant if a house is rented. The amount depends on: (a) the rateable value, and (b) the rate in the £ levied by each Council. The latter varies widely Council by Council, and is liable to annual or even half-yearly change.

**Rateable Value.**—Under a comprehensive re-valuation completed in 1955 all dwellings have been reassessed on a common basis laid down in the Valuation for Rating Act, 1953. The starting point is the *Gross Value*, which is the rent at which the property might reasonably have been expected to let at end-June 1939, with: (a) the tenant paying all usual tenant's rates and taxes (but excluding income tax); and (b) the owner meeting the cost of repairs and insurance. A *Repairs Allowance* is next given at fixed scales. The net figure left is the *RATEABLE VALUE*, and it is the one on which rates are paid. The new values came into effect as from April 1st, 1956. Ratepayers may appeal for reductions in the gross value at any time during the currency of the rate. This right is particularly important when a new

house is first valued. An appeal must first be made to the local Inland Revenue Valuer, whose address is obtainable from the town hall or council offices.

If the valuer's decision is unfavourable the appeal can be carried to the local Valuation Court. A final appeal can be made to the local Land Tribunal, which, however, may entail certain costs. A qualified rating valuer should be consulted in complicated cases.

## 8. INCOME TAX.

**Net Annual Value.**—Income Tax assessments on property, made separately by the local Commissioners of Income Tax, also start with a *Gross Value*, which can be defined as the fair rental value with the tenant paying rates and the owner repairs and insurance. (The income-tax figure, it should be noted, is not necessarily the same as the rating gross value.) A repairs allowance (automatically given) is based on the gross annual value, as under:—

G.A.V.	Repairs Allowance
Up to £40	One-quarter of the G.A.V.
£40-£50	£10.
£50-£100	One-fifth of the G.A.V.
Over £100	£20, plus one-sixth of the G.A.V. over £100.

The balance, known as the *Net Annual Value*, is the amount on which Schedule A, or Property Tax, is assessed.

**Appeals.**—An appeal for a reduction in the gross annual value can, as with rating valuations, be made by the owner at any time. When a new house is assessed for the first time an appeal must be made within forty-two days of receipt of the notice. All appeals should first be made to the local Inspector of Taxes and, if no satisfactory agreement can be reached, taken next to the local General Commissioners of Income Tax.

**Relief for Repairs.**—Rebates may be claimed for repairs when actual expenditure over specified periods exceeds the fixed allowance. The normal basis for making what is called a *Maintenance (or Excess Repairs) Claim* is the average spent over five consecutive years, generally ending March 31st. After making the initial claim, subsequent claims are made year after year by dropping out the expenditure for the earliest year and adding that for the newest, until the five-year average drops below the fixed allowance. One useful exception to this general rule may apply where a property has been owned for less than five years and a lot of money has been spent on it. If the previous owner's expenditure is known it can be included with such outlays to arrive at the five-year average. Alternatively, it may be possible to arrange with the Inspector of Taxes to work on actual yearly expenditure until a full five years' figures are available. All claims must be supported by receipted and detailed bills, which should always be kept. The cost of insuring the house—but not the contents—should be included. Money need not be spent each year; it is the five-year average which matters. Claims must be made by the owner within six years of the end of the relative tax year to the local Inspector of Taxes.

**How the Owner Pays Income Tax.**—When it comes to calculation of the income-tax liability on a house the net annual value is taken into account as part of the owner's income. Tax, if any, is then payable at the rate or rates applicable to the total income from all sources after deduction of personal and other allowances and reliefs. The owner obtains relief, in addition to any maintenance relief, in respect of the annual interest paid on a mortgage or loan on the security of the house. If the interest is paid to a building society, local council, certain insurance companies or a bank, relief will be given normally by setting off as much as possible against the assessment on the house and the balance, if any, against other in-

come. But if the mortgage is the type where income tax is deducted from each interest payment such tax will have to be paid over to the tax collector and the assessment, or part of it, will remain. Though this seems to be a complicated way of doing things, the net effect is the same and full relief is given. All queries about property tax assessments should be addressed to the local Inspector of Taxes.

## 9. GRANTS FOR IMPROVEMENTS AND CONVERSIONS.

**What Grants Cover.**—Grants towards the cost of certain types of improvements and for conversions can be made to property owners by Local Authorities, the Government paying approximately three-quarters of the amount and the Council the balance. *Improvement* for this purpose means work, other than ordinary repairs, necessary to bring a dwelling up to reasonable modern standards of convenience and comfort. It includes such essentials as installation of indoor water supplies, bathroom or indoor w.c., gas or electricity from a nearby main, hot-water system, standard kitchen equipment, and new windows to improve ventilation or lighting; putting right any fundamental defects in the structure; and provision of proper food and fuel storage. *Conversion* work includes the division of a suitable house or group of houses into flats or other self-contained dwellings.

**Conditions of Grant.**—To qualify for a grant council approval must be obtained before any work is started. The property must be brought up to certain defined standards and usable life and the estimated cost of approved work must be more than £100. The maximum grant for each dwelling provided is one-half the approved cost or £400, whichever is less. Fees for professional help and advice may be included in the approved cost.

## 10. PROTECTION OF DEPENDANTS AND HOME BY ASSURANCE.

**Freedom from Debt in Case of Death.**—Life assurance can be linked with house purchase in various ways to provide not only finance, but protection for dependants and, perhaps, a fund for meeting major expenditure some way ahead. A popular method is a loan from a life insurance office repayable by means of an endowment assurance. It is a two-way transaction. The insurance office makes a fixed loan for an agreed number of years. Simultaneously, the borrower takes out an endowment assurance for at least the same amount and the same period. Thus—which is the great merit of this method—if he dies at any time after paying the first premium the endowment pays off the mortgage and leaves the house free of debt. The maximum maturity period of the endowment assurance is normally twenty to twenty-five years or age sixty-five, whichever is the shorter term.

**Home Protection Insurance.**—A growingly popular and cheaper method of "insuring" reducing types of loan is, however, a reducing-term insurance, more popularly called "mortgage protection," "home protection" insurance, and so on. Though a number of variations are available, the basis is similar—the amount assured falls annually as the mortgage is reduced. Under the simplest form the insurance provides enough to repay the balance of the mortgage if death occurs before its complete repayment, but the borrower obtains no cash benefit if he lives to the end of the term. Premiums, payable for only a limited number of years, vary according to the age of the borrower and rates for younger age groups are no more than a few pounds per £1,000 original loan. The need to insure your house and contents is explained in Part III.

### III. A GUIDE TO INSURANCE

It is simple prudence to secure the benefits of insurance. You should ask yourself not whether you ought to insure but which pattern of insurance suits you best. Life assurance will give you confidence and your dependants too; and this will promote that trust which makes for happy relationship. Moreover, life assurance is a form of systematic saving against the inevitable rainy day. And there is a special word of advice for women, who are naturally especially concerned about financial security.

The figures quoted are those ruling at the time of writing (September 1955).

**Life Assurance: Who may Insure.**—You may insure your life and thus provide for your family in the event of your early death. A husband may take out an insurance on the life of his wife, and vice versa. It is a condition of the grant of a life policy that the person effecting it should have an interest in the life to be insured, known as an insurable interest. Every adult person has an unlimited insurable interest in his or her own life. A husband has an unlimited insurable interest in the life of his wife, and vice versa. These are, however, exceptions to the general rule, which is that the interest must be pecuniary, i.e., measurable in terms of money. Relationship in itself does not constitute an insurable interest. Thus a parent as such has no insurable interest in the life of his child, nor a child in the life of its parents. It is to be noted that provided the insurable interest subsists at the time the policy is effected, the interest may be reduced or disappear entirely during the term of the policy without invalidating the contract.

**"With" and "Without Profit" Assurance.**—Both whole-life and endowment assurances can be obtained either with or without the right to participate in profits, termed bonuses, a larger premium being charged for participation. A policy-holder's share in the profits is usually added to the sum assured. It is known as a reversionary bonus, and is payable with the original sum assured at the time of claim. These bonuses may, if desired, be surrendered for immediate cash without disturbing the original assurance, but the cash value, is, of course, considerably less than its reversionary value as an addition to the sum assured. The bonus may be calculated as a "simple" bonus on the sum assured or as "compound" bonus on the sum assured and any bonuses already added.

**Whole Life Assurance.**—The first contract should provide life assurance for as long as it can possibly be needed, which generally means a whole of life policy. The premiums may be payable throughout the lifetime of the assured, or can be limited to a fixed term of years, when, if the life assured survives beyond the fixed term, the policy continues in force without further payments of premiums. A whole-life policy under which premiums are payable throughout the life of the assured, and which does not participate in profits, is the cheapest form of permanent life assurance because it provides the maximum sum assured with the minimum premium outlay. A whole-life policy, either with or without profits, and preferably with premium payments ceasing not later than retirement age, should form the backbone of every well-planned scheme of life assurance. At age 25 a whole-life "without profit" policy for £1,000 will cost around £15 a year subject to rebate of income tax, or, say, £17 a year if it be arranged for premiums to cease at age 65. If effected on the "with profit" plan, a whole-life policy for £1,000 with premiums payable throughout life will cost about £22 at age 25, or around £24 a year if premium payments cease at age 65. The bonus additions to the sum assured, although not guaranteed, should average some £20 a year, or may exceed this estimate. A whole-life policy can be used as collateral security for repayment of a loan in the event of death of the borrower; to secure an estate against the impact of death duties; or a business against possible difficulties by withdrawal of capital upon the death of a partner.

**Endowment Assurance.**—In its simplest form an endowment assurance secures a stipulated sum upon the survival of the life assured to a stated date, or upon his death should that occur earlier. The most important advantage of endowment assurance is provision for old age. Where adequate assurance has already been effected as a provision for dependants, a short-term endowment assurance is often the best means of making provision for school expenses or providing a child with a start in life. But apart from special circumstances of that kind, the best form of endowment assurance in the great majority of cases is a policy maturing at the prospective age of retirement. Many men, of course, come under a pension scheme, but the pension will by no means equal their earnings, and may die with them. Their wives may enjoy the protection of a widow's pension, but this is likely to be a modest amount and perhaps inadequate, even allowing for an amount under the National Insurance scheme. There is therefore no better object for your savings than an endowment assurance maturing at 65. It provides a reasonable amount for dependants in the event of early death, while if the assured survives to 65 he receives a capital sum, when he can convert the policy moneys into a pension for himself, or himself and his wife.

**Endowments by Instalments.**—The proceeds of an endowment assurance may be payable by instalments over a period of, say, 5, 10, or 15 years free of income tax. The person assured would, of course, have an option to take a lump-sum payment at maturity instead of payment by instalments, and his representatives could make such a choice in the event of his death during the policy term.

**Optional Endowments.**—An option to convert to an endowment assurance can always be attached to a whole-life policy, so that if at the end of, say, five or ten years an endowment would better suit the assured's needs, the change can then be made. The option is with the assured, and if ill-health has overtaken him since effecting the whole-life assurance, he will no doubt prefer to retain the cheaper form of policy. This freedom of choice is of great value whether the policy is intended as a complete provision in itself or whether it is to be used in combination with other policies.

**"Income" for Dependants and Retirement.**—The "family-income" type of policy has been devised because it is when the family is young that it needs the most support. There is a plan to suit every need and every purse. Although some offices assure "income" independently of "capital" provision, the most beneficial plan is where the income benefits form part of a whole-life or long-term endowment assurance, to which the income benefits may be added at any time. At age 30 next birthday, an annual premium around £22 payable during the first 20 years and then reducing to around £17 will provide, in the event of death of the assured within 20 years, a tax-free payment of £150 per annum by monthly instalments for the remainder of that period, and, in addition, a cash sum of £1,000 at the end of the income benefit period. If death occurs after 20 years from the commencement of the policy, a cash payment of £1,000 is made at death. There are various varieties of this principle.

**Financial Security for Women.**—An increasing number of women are effecting policies, both as provision in the event of death as well as for old age. The woman following a career can provide for retirement at 55, or, at the latest 60, by an endowment assurance, or by what is known as a double-endowment assurance, or by the purchase of a deferred annuity. The two former have the advantage of tax rebate not allowable on premiums under a deferred-annuity contract. For a young woman the problem is: "If I marry, a policy on my husband's life is important. If I do not marry, a pension for myself is necessary." For this situation a number of special assurance schemes have been devised. Under one such

scheme a single woman assures her own life for a sum payable, either with or without bonus additions, at 55 or 60, and has the option, should she marry, to exchange the assurance for one on the life of her husband. By another, she has the option on marriage to take a small cash payment and, subject to her husband's not having reached 45, can exchange the policy for an assurance on her husband's life. In both cases the substituted policy remains for her absolute benefit, and is issued without medical examination of the husband or other evidence of his health.

**Assurances for Children.**—The cost of education can be met by an endowment assurance on the life of the parent or guardian. There are special assurances available with the sum assured payable at *termly* intervals over a period of years. In the event of premature death of the parent or guardian premiums cease at once, and the education fees provided for would then commence, or, alternatively, fees of the original period of the assurance. The ordinary rebate of income tax can be claimed on the premiums of these policies.

**Child's Deferred Assurance.**—A popular form of policy for the benefit of a child on reaching maturity is the child's deferred assurance, which becomes the property of the child on becoming 21 or 25, when a number of valuable options may be exercised. The most valuable option permits the assurance to be continued on a whole-life or endowment basis—with or without profits—at the same low premium, irrespective of the state of health of the child at that time, and without regard to occupation, travel, or foreign residence. The policy may thus be said to provide insurance against uninsurability, and this possibility is a very real one. The policy sometimes carries a special educational option at, say, 15, to meet school fees. Varying schemes of this nature are offered at comparatively small premiums, often no more than £10 per annum, or £1 per month. A small extra premium, which varies with the age of the parent, will provide that, if the parent dies, all premiums cease up to the option age. No loss can be sustained under this class of assurance, for all premiums paid are returned should the child not survive to the agreed "option age."

**Life Assurance and House Purchase.**—No man should buy a house on mortgage without making sure that, in the event of his death before the mortgage has been paid off, his wife and family will be free from any liability in connection therewith. The only way to safeguard one's dependants is through life assurance, and particularly by means of a life policy specially adapted to the purpose. Enquiry should be made as to the various kinds of assurance for this purpose.

**Loan, Surrender, and Paid-up Values.**—Both whole-life and endowment assurances acquire a surrender value after a minimum number of annual premiums (usually two or three) have been paid. Alternatively, either type of contract can be converted into a paid-up policy, i.e., the payment of future premiums is dispensed with, but, of course, a reduction is made in the sum assured. The surrender value of a whole-life or endowment assurance increases as time passes, and provided that premiums are regularly paid, policies form good security for a loan either from the office itself or from a bank. This may prove very valuable in the event of temporary financial embarrassment. Policies acquiring a surrender value are in general subject to special conditions of considerable value to the policy-holder in the event of premiums not being paid when due. Under what are termed "non-forfeiture regulations" the accrued surrender value is applied automatically to keep the assurance in force. The non-forfeiture period lasts so long as there is a surrender value sufficient to cover the unpaid premiums.

**Income-tax Allowance.**—Under existing legislation relief of income tax may be claimed on the amount of the premiums paid for life assurance effected by a person on his own life or on the life of his wife subject to the following conditions:

1. The amount on which relief is allowed is not to exceed one-sixth of the total income.
2. No allowance will be made in respect of

that portion of any annual premium which is greater than £7 for each £100 assured if the annual premiums are £25 or more.

Subject to the above conditions, an allowance of income tax is granted as under, calculated at the highest rate of tax paid, i.e., 2s. 3d., 4s. 9d., 6s. 9d., or 8s. 6d. in the £ (in border-line cases the allowances will be partly at one rate and partly at another):

(a) When premiums eligible for relief do not exceed £10 annually, tax allowance is made on the actual premiums paid.

(b) When premiums exceed £10 but do not exceed £25 annually, tax allowance is made on £10 only.

(c) When premiums exceed £25 a year, tax allowance is based on two-fifths of the premiums paid.

It was proposed in the 1956 Budget to give relief from tax in respect of premiums paid to provide retirement annuities in the case of self-employed persons and employees not in pensionable employment.

**Fire—Burglary—Accident—Personal Liability.**—The householder can incur heavy losses through fire, burglary, storm, flood, and burst pipes, or maybe Common Law liability to servants or temporary and occasional employees about the house, or, as owner or occupier, to members of the general public. The householder should therefore effect an insurance on both building and contents against these and other risks under an appropriate comprehensive policy. A comprehensive policy—whether on buildings or contents or on both—gives a wider cover and is cheaper than separate policies. A liability with the possibility of heavy loss is that of a house-owner to the public arising out of accidents resulting in bodily injury or damage to property, for which the comprehensive insurance grants indemnity up to £25,000, with costs and expenses incurred additional. The normal comprehensive rate is 2s. 3d. per cent. on the full value of the building and 5s. per cent. on the value of contents.

**Accident and Sickness Insurance.**—Accidents mean lost earnings during incapacity, and often even in these days of the Welfare State, medical and surgical expenses. Personal accident and sickness insurance is therefore of undoubted value. Various schemes are available with premiums ranging from, say, £2 a year, according to the cover granted and the occupation of the proposer. The main types of cover are:

- (a) an accidents only policy;
- (b) an accidents and specified diseases policy;
- (c) an accidents and all-sickness policy;
- (d) a permanent sickness and accident policy.

These schemes are year-to-year contracts, renewable each year being at the option of the company. A permanent non-cancellable sickness and all-accident policy is available under which the company guarantees continuous cover to a given age whatever the sickness record may be. A permanent contract of this nature is particularly suited to the professional or business man, who, whilst able to command a substantial income so long as he is physically fit, would suffer considerable loss of earning power, and perhaps complete loss of income, in the event of a prolonged breakdown in health. The non-cancellable form requires a somewhat higher premium than the year-to-year contract, and is only issued by certain specialist companies after the proposer has been proved in good health by medical examination.

**Personal Liability.**—In daily life individuals may incur legal liability in many circumstances. If the individual is negligent, and through his negligence some other person suffers injury or damage to property, the negligent party may be responsible and have to make redress. Instances of this nature have increased considerably in recent years. Even where negligence is not proved, the cost and worry of defending a claim is something to be avoided by the layman. The proposal form of personal liability insurance is very simple, often requiring no more than the name, address, and signature of the proposer.

# Sports and Pastimes

By JAMES AUDSLEY

## INTRODUCTION.

THE field of sports, games, and pastimes is such a vast one that no editor of a work of this kind, with but one section of the volume at his disposal, can hope to cover everything in it. Omissions being unavoidable, it was, therefore, necessary to work out a plan that would give as wide a coverage as possible, within the limits set.

The first step was obviously some kind of division of the subject into sub-sections; and the obvious choice was Outdoor Games and Indoor Games. Some sports, however, such as basketball, boxing, wrestling, weight-lifting, etc., though played indoors, seemed to belong more with outdoor sports such as athletics and football than with games like bridge and chess: so the final decision was, first, Sports and Outdoor Games, followed by Indoor Games and Pastimes.

Then came the problem of limiting the field. In the outdoor section, it was decided to omit all sports in which competitors depended upon mechanical aid in addition to their own skill. This ruled out such things as aeroplane racing, motor racing, motor-boat racing, and motor-cycle racing. Speedway racing thus had to be left out too, for it would have been manifestly unfair to include this, while omitting other types of motor-cycle racing. Sports using horses are also omitted. A proper description of a vast subject like racing was out of the question; and the inclusion of driving, trotting, and polo seemed inappropriate without racing. Greyhound racing, a sport in which no one can actually participate, is also excluded.

Most games popular in Britain are described as clearly as is consistent with reasonable brevity; and certain games which are fairly recent arrivals from abroad, such as baseball, basketball, ice-hockey, and korfbal, are included. Some mention is also made of overseas versions of certain games, such as the American, Australian, and Canadian brands of football. It was also thought desirable to include some records, but, with the material for this work having to be prepared some time in advance, the choice was not an easy one. There are, however, lists of current Olympic and European athletic champions, who, of course, hold their titles for four years.

The indoor field is so vast that selection had to be almost completely arbitrary. With cards, for instance, there are games of sheer skill, games of pure chance, and games at every level between these two extremes. There are also many games which actually derive from and resemble each other. Bridge, the most widely discussed and widely played card game, has first claim to inclusion. Whist, which might be called the basic card game, is the only other card heading, but more than one game is included under it.

Amongst board games, history, tradition, and the sheer skill which it demands guarantee the inclusion of chess. Using the same board and also extremely popular is draughts, which is also described. Darts could hardly be omitted, and is not; and shove ha'penny also finds a place.

In addition, there is a selection of Old English Games, some of them still played to-day, others of interest as they are so clearly ancestors of games played to-day. They are a varied collection: so the Pastimes sub-section seemed the most suitable place for them.

## SPORTS AND OUTDOOR GAMES

### ATHLETICS.

The sport of athletics, which comprises competitions in running, walking, jumping, and throwing, is really the most natural of all sports. Walking and running, the one only an intensified form of the other, are perfectly natural physical movements, and a glance at children at play will soon satisfy any doubts as to whether or not jumping and throwing also come into this category.

The history of athletics actually starts in the days of pre-history, or of mythology. We have details of the Olympic Games of 776 B.C., and it is certain that the Games were being held before this—perhaps long before this. The story of athletics from before the Olympic Games of 776 B.C. to those of today, however, is not a continuous one. The Greeks were followed by the Romans, who discontinued the Olympic Games: so the historian seeking the beginnings of the present-day sport might then turn to the country sports of various periods of English history. There were such sports, and they included some races, but they did not really give very much indication that they would lead to athletics as we know it to-day.

The true beginnings of athletics can be found almost exactly a century ago: for it was in 1849 that the Royal Military Academy, Woolwich, instituted a sports meeting, and a year later that Exeter College, Oxford, gave a lead that was soon to be followed by the other Colleges of Oxford and Cambridge. The Civil Service were also early in the field, and the first actual athletic club to be formed was the Mincing Lane Athletic Club, which is still active to-day as the London Athletic Club. There was also an organisation called the Amateur Athletic Club, which ran an annual championship meeting which was to all intents and purposes a national meeting. Then, in 1880, the Amateur Athletic Association was founded. It took over the organisation of the annual championships, and started the government of the sport which it still

rules to-day. Other countries, particularly the United States, were soon in the field, and, in 1896, the first modern Olympic Games took place at Athens. Subsequently the Empire Games, the European Championships, the Balkan Games, and many other international meetings and matches came into being; and championships and competitions of all standards were instituted in almost every country in the world.

Athletic events have now become standardised so that races are generally at one or another of a series of recognised distances, and throwing and jumping events are held in accordance with certain internationally agreed rules. With regard to races, there are actually two lists of standard events, one being in the yards and miles of British and American measurement, and the other in the metric equivalents of these distances. Some idea of the scope of the sport can be gained from a list of the events included in the A.A.A. Championships and from those included in the Olympic Games.

The A.A.A. Championships consist of: 100 yards, 220 yards, 440 yards, 880 yards, 1 mile, 3 miles, 6 miles, Marathon (standardised at 26 miles 385 yards—not the distance from Marathon to Athens, but that covered in the Olympic race of 1908, just when the desirability of standardising the distance was becoming apparent), 120 yards hurdles, 440 yards hurdles, 3,000 metres steeplechase, high jump, long jump, pole vault, hop-step-and-jump, putting the shot or weight (16 lb.), throwing the hammer (16 lb.), throwing the discus, throwing the javelin, 440 yards relay (4 × 110 yards), 1 mile relay (4 × 440 yards), 2 miles walk, 7 miles walk, and Decathlon.

The events in the athletic section of the Olympic Games are: 100 metres, 200 metres, 400 metres, 800 metres, 1,500 metres, 5,000 metres, 10,000 metres, Marathon, 110 metres hurdles, 400 metres hurdles, 3,000 metres steeplechase, high jump, long jump (called the broad jump in the United States), pole vault, hop-step-and-jump, shot-put, throwing

the hammer, discus and javelin, 400 metres relay (4 × 100 metres), 1,600 metres relay (4 × 400 metres), 20,000 metres road walk, 50,000 metres road walk, and Decathlon.

The Decathlon is an all-round test in which the competitor has to take part in ten events, the 100 metres, 400 metres, 1,500 metres, 110 metres hurdles, high jump, long jump, pole vault, shot-put, throwing the discus, and throwing the javelin, all within two days, and score points in each or else retire from the competition. This, the severest test of strength, speed, stamina, and fortitude to be found anywhere in the whole world of sport, was won at the Olympic Games of 1948 by Bob Matthias, an American then aged seventeen.

Walking has actually a governing body of its own, the Race Walking Association, though, as will have been noted, there are track walking races held under the auspices of the A.A.A. Some walkers concentrate on long road races all the year round, but the majority take part in road races during the winter and shorter track races during the summer. The road season is carefully organised so that almost all races arranged early in the season are at 7 miles. Later on, this increases to 10 miles, and, at this stage, the R.W.A. 10 miles championship and 10 miles junior championship take place. Distances continue to increase, and there is a championship at 20 miles. The final championship, which takes place early in the summer when the track season has already started, is the 50 kilometres, and this attracts chiefly the confirmed, all-the-year-round road walkers. There are regular races from London to Brighton, and, every four years, there is a race from London to Brighton and back—actually from Croydon to London, then to Brighton, then back to Croydon.

Athletics is mainly a summer sport, and many runners turn to cross-country running—governed by the English Cross-Country Union—during the winter. There is a vast annual programme of matches and championships, the latter including County championships, an Inter-County championship, North of the Thames and South of the Thames championships, Northern, Midland and Southern championships, National championships for seniors, juniors and youths, and the International championship. This last used to be between England, Scotland, Ireland, Wales, France, and Belgium, but, in recent years, several other countries have entered as well. Major cross-country championships are over courses of about 10 miles.

Athletics is entirely an amateur sport, controlled in England and Wales by the A.A.A., and in Scotland and Northern Ireland by similar bodies, the three Associations combining to form the British Amateur Athletic Board. There is some professional running, i.e., races with money prizes, but this side of the sport is called, not athletics, but pedestrianism. There is a famous annual professional meeting at the Powderhall Grounds, Edinburgh, and there are some other events in Scotland and the North of England. There are also a number of regular meetings with big prizes in Australia, chiefly in Victoria.

Women also take part in athletics, though they do not, of course, compete in very long races, nor do they throw the men's heavy implements. The Women's Amateur Athletic Association was founded in 1922, and women's events have been included in the Olympic Games since 1928.

## BASEBALL.

Baseball, a summer game with a season running from April until October, is the national game of the United States. The original invention of it is credited to an Army officer, and it has developed from old country games called "One Old Cat" and "Two Old Cat" to the highly skilled, fully commercialised sport of to-day.

Teams are nine-aside, and they take turns in batting and fielding. The main part of the ground is the "diamond." This is an area marked at each corner of the diamond by a "base," which is a sack fixed to the ground, the lines from sack to sack being the "base paths." One of these bases is known as "home," and here the batter stands, by a square of rubber on the ground, which is known as the "plate." The base which is forward and to the right of a right-handed batter is "first," the one straight ahead of him "second," and the

one forward and to his left "third." Each base is 30 yards from its nearest neighbours. Between first and third and 20 yards out straight in front of the plate is the pitcher's "mound." The lines from home to first and from home to third are continued beyond these bases, and are the "foul lines." It is the object of the batting side, using a bat which resembles a very long and heavy Indian club, to hit the ball, which is white in colour, hard, and weighs 5 ounces, and to score runs, one being scored each time a member of the team completes the circuit of the bases, not necessarily from one hit. The team bats in an order arranged before the start, each batter being succeeded by the next as he leaves the plate, either "out" or to proceed to first base or further still. A game consists of nine innings, each innings being completed when three men are out, and each succeeding innings starting at whatever place in the batting order has been reached. The batting order is a continuous one, number one following straight on again after number nine. Should the team batting second score more runs in eight innings than their opponents do in nine innings, then the last half of the ninth is not played. There is no toss for first innings, the visitors always batting first.

The fielding side is divided into three sections, the "battery," the "infield," and the "outfield." The battery consists of the pitcher and the catcher who stands behind the batter. The infield, four strong, consists of the first baseman, at or near first; the second baseman, between first and second; the short-stop, between second and third; and the third baseman, at or near third. The remaining three fielders, out well beyond the infield, are the right, centre, and left outfielders. Each fielder wears a glove on one hand, that of the arm which he does not use for throwing, the catcher and the first baseman being allowed larger gloves than the others. The catcher also wears a chest protector and a mask.

The ball delivered by the pitcher to the batter reaches him without touching the ground. Should it pass over the plate between the batter's shoulders and knees without being hit, it is a "strike." Three such strikes dismiss the batter. Should it pass wide of the plate or too high or too low, it is a "ball"—unless the batter makes a stroke at it, when it becomes a strike if missed. Four balls give the batter a "walk," i.e., a free passage to first base. The batter must run—to first, or farther if he can get farther—if he hits, but he cannot run if the hit goes foul. It must be hit in front of him and between the foul lines. If it passes over the foul lines it is a "foul hit," while, if he snicks it so that it goes behind him, it is a "foul tip." The first and second foul hits are counted against him as strikes, but the third strike that would actually dismiss him cannot be by a foul hit. Any foul hit by a batter who already has two strikes on him does not count, unless it is caught, for a batter may always be caught out from any hit. He can also be "put out" when running the bases, this happening when a fielder, in possession of the ball, goes to the base for which the runner is making and "tags" him as he comes in.

It should be noted that the ball is not dead when an out is made. A man making a catch can still throw the ball to a baseman in the hope of running out another player, and that baseman, having made the put out, can relay the ball to still another team-mate for the same purpose. In this way, it is possible, though it is rare, for the fielding side to make the three outs which complete an innings in one "play." "Double plays" are quite frequent. If there are several runners on the base paths, a fielder will always throw to put out the man running for home, if possible, as otherwise this runner will actually score. If, however, there are already two out, it is not necessary to concentrate on the scoring one of, say, two runners. Any out made at that point ends the innings, and no runs scored on that actual play count. Only one man can occupy any base at one time, so it follows that, if there is a man on first when a batter is walked, then this player must proceed to second. If all the bases are occupied—"full" or "loaded" are the terms used—then a walk will automatically force in one run. Except when this would occur, pitchers often deliberately walk known dangerous hitters.

Once there are runners on the bases, the pitcher's job becomes more complicated. These runners may move at any time, and one or more may attempt to "steal" a base. If this is tried, the pitcher will throw the ball to the appropriate base, instead of pitching to the batter. The catcher will also be watching for an attempt to steal. If he sees one, he will immediately move from behind the batter and call for a "pitch out." The pitcher will throw the ball to him, and he will relay it to the appropriate base. The batting side will have players not actually engaged or coaches coaching at first and third, and advising the runners when to steal. A batter may deliberately "sacrifice" himself to advance a team-mate on the base paths. He does this by hitting the ball gently—"bunting" is the term—towards the pitcher or down the first base line. He is, of course, automatically put out at first, but one or more colleagues may have advanced one or more bases while the ball was rolling. Obviously, this would not be done with two out, as a third would end the innings, and no advance by other runners would be of use. Runners on bases when an innings ends are said to be "left on," and they score nothing. Incidentally, if a batter is hit by a pitched ball, he gets a free passage to first.

Substitutes are permitted, and pitchers who are being hit are often relieved. Spare pitchers will be "warming up" with spare catchers in a special area known as the "bull pen." Also a team desperately in need of runs may want to make a batting change if the lower part of the batting order is "up." Pitchers, being specialists, are rarely good hitters, and if there are men on base who might score, two out, and it is the pitcher's turn to bat, it may be expedient to send in another batter, not one of the actual line playing the game, as a "pinch hitter." If this is done, then a different pitcher must be used when the side fields again.

Although the pitched ball reaches the batter full pitch, pitchers can develop a wide variety of pitches, including very fast balls, curves, etc. It is the catcher, who knows his own pitchers and who studies the strong and weak points of the batters, who chooses what type of ball should be pitched, and this is indicated to the pitcher by a signal, which might be, for instance, two fingers held against the glove in a certain way. The pitcher may accept or refuse a signal. If he refuses and it is repeated, he will know that the catcher considers it urgent that that particular delivery be thrown. Refusals are most frequent when the catcher calls for a fast ball near the end of a game, when the pitcher is tiring. Incidentally, a batter is not automatically struck out when the third strike crosses the plate. He is not out until the catcher, who will be credited with the put out, catches the ball. If he fails to hold it, the batter may run for first, though he will seldom reach there before the catcher gathers and relays the ball.

Detailed score sheets are kept, and against each player's name is shown: his times at bat; his hits; how many of the hits were one base hits (singles), how many two base hits (two-baggers), how many three base hits (triples), and how many four base hits (home runs or homers); how many runs he actually scored; how many runs he batted in, i.e., the number of men who crossed the plate after completing their circuit on his hits; how many sacrifices he made; how many put outs he made when fielding; how many assists, i.e., throws which resulted in a put out; and how many errors, i.e., fumbles, dropped catches, throws to the wrong base, etc., he made. Against the pitcher's name will be shown the number of innings pitched; the number of runs scored against him; the number of hits off him; the number of walks given; and the number of men actually struck out. Batting averages are calculated by dividing the times at bat into the number of hits. An average of 0.400 would be exceptionally good. Pitchers are graded according to the number of games won and lost. The word "hits" in these scores always means a safe hit that took the batter to first base or farther still, and was not a chance. If a batter hits a catch and goes safely to first base because the catch was dropped, he remains at first and plays on from there in the usual way, but he is not credited with a hit.

The game in America is highly organised. There are two major leagues, the National and the

American, each consisting of eight clubs. Each club plays a schedule of 154 games, meeting each of the other clubs in its league 22 times. Games are played every day, including Sundays. The champions of these two leagues meet in a series of the best of seven games, known as the "World Series," for the Championship of the World. Below these two leagues, are two others, the International—so called because two of the teams are in Canada—and the American Association. The champions of these leagues meet in the "Little World Series." Underneath these are numerous professional leagues, classified A, B, C, or D according to the standard of play. Then come the semi-professional clubs and the "sandlot" or amateur teams. The clubs in the major leagues will have an extensive "farm" system, consisting of clubs owned and run by the major organisation in junior leagues of every grade. Promising players will be brought up to major standard through this chain.

Baseball is also the chief summer game of Canada, and it is very widely played in Australia. It has been played in Britain for some years, and, since the war, it has made very considerable progress. There are clubs in almost every part of the country, and games have attracted crowds of up to 20,000. The game may well equal the popularity of cricket, for it is full of action, and games rarely have to be left drawn, as a full match is usually completed within two hours.

Similar to baseball is Softball, which is very popular in America with girls as well as men, and which was demonstrated in Britain during the war by American and Canadian servicemen. The ball is not actually particularly soft, but it is larger than a baseball, and all pitching is underarm. Distances between bases, and between the plate and the mound are shorter than in the parent game.

## BASKETBALL.

Basketball is an ideal example of the winter team game, which is also primarily an indoor game. Originally invented by an American Y.M.C.A. official at Springfield, Massachusetts, it can be played in almost any gymnasium or hall; and it can be played outdoors on an asphalt court. In America it is played by teams of all standards from schoolboys to professionals; and, taking games all over the country into account, it is watched by more spectators than any other American game. In the country of its birth, it can justifiably be called the chief winter team game, especially having regard to the facts that ice-hockey is played only in certain sections of the country, that American football has only a ten-week season finishing early in December, and that lacrosse is played only in the spring. Basketball has spread far beyond the United States, and it is played in almost as many countries as is Association football. It is included in the Olympic Games, and, in the Games of 1948, the basketball tournament occupied the whole Olympic fortnight. It has been played in Britain for some years, and is on the increase. There are specially active centres in London and Birmingham, and the Services, particularly the R.A.F., have taken it up as part of their physical-training schemes, and have helped to popularise it.

Basketball is played five-a-side, but substitutes are permitted. The ball resembles that used in Association football, but it is played only with the hands. The goals consist of posts with iron rings at the top, through which the ball must be thrown. These rings have short nets suspended from them, and the ball must, of course, pass through the rings from above them. Fixed to the top of the posts behind the goals are back-boards, and the ball may be thrown against these so as to fall down through the ring. Running with the ball is not permitted, and it is advanced by dribbling, which means by bouncing it, or by passing. Some hard knocks are inevitable, and most players wear elbow and knee pads. Deliberate bodily contact as a means of defence is not, however, allowed; and the penalty for a "personal" foul is two free throws, while, for a more technical infringement, it is one free throw. Goals thrown during play count two points, and goals thrown from free throws are worth one point. Tactics play a big part in the game, and most teams try to carry out attacks according to a prearranged plan. Defen-

sive plans are also made, these being based on either a man-to-man or a zone defence. Stamina and agility are both needed for basketball, and great height is an asset. There are teams in the United States in which a man 6 feet 4 inches tall would be the smallest man playing.

Basketball has been enthusiastically taken up by girls in the United States and in some European countries, but not as yet in Britain.

### Netball.

Similar to basketball, and, as far as Britain is concerned, very much older, is netball. Unlike basketball, which, though it is played by girls, is primarily a men's game, netball is exclusively a girls' game. It is almost always played outdoors on an asphalt or even a grass court. The ball is similar to that used in basketball, as are the goals, except that these have no back-boards. Netball is played seven-aside instead of five, and substitutes are not permitted.

### BOWLS.

Bowls is one of the oldest of all games, and, like several other almost traditional games, it seems to be steadily increasing in favour in these middle years of the twentieth century. Once dismissed by many people as simply "an old man's game," it now has many devotees of all ages and also of both sexes. It is played indoors as well as out, for there are now several covered rinks operating in various parts of the country. The game certainly goes back to the thirteenth century, and, in its earlier days, its popularity was such that it was one of the games officially legislated against as likely to attract people away from archery. Henry VIII., who was fond of all sports, was a keen player; and the famous game on Plymouth Hoe in which Sir John Hawkins brought his match with Sir Francis Drake to a successful conclusion even after the Armada had been sighted, if not definitely authenticated, is accepted as fact by several competent historical authorities. About a century after this incident, however, Bowls fell on evil times. Many greens were attached to taverns, and the game acquired a reputation as being merely an adjunct to pothouse revelry. It was revived on a rather higher level in Scotland, however, never again to sink so near to oblivion.

Bowls as played to-day is actually two separate games, and each has its own supporters, few players of one attempting the other. These are the Rink or Level Green Game and the Crown Green game. As the names imply, it is the rinks rather than the basic objectives of the games which differ. The Level Green game is the more widely played, and this, as the name suggests, is played on a perfectly flat piece of well-cared-for turf. The Crown Green game, which is very popular in Lancashire and Yorkshire and which is also played in the Midlands, is played on a green of which the centre is 6 inches or more higher than the corners. There are some differences in the actual games—for instance, in the putting into play of the object ball—but basically the two games are similar, so it will be appreciated that a good deal of experience and a very high level of skill is demanded by the Crown Green. This game is usually played between two players who oppose each other, whereas the Level Green game is played between sides each consisting of one, two, three, or four players.

The particular equipment used and the detailed technicalities of Bowls make it a game in which a great deal of skill can be attained, but at first glance it seems a very simple game. Its object is simply the playing of the bowls as near as possible to the object ball. Bearing in mind, however, first, that the object ball itself does not occupy a fixed spot but is put into play by the first player, and, secondly, that the bowls are biased, it will be realised that the elementary objective is more easily planned than achieved.

The object ball or "jack" is a small white ball about 2½ inches in diameter. The bowls used differ in the two games. Those in the Level Green game have a maximum weight of 3½ lb. and a maximum circumference of 16½ inches. Those in the Crown Green game are much smaller and lighter. They are also less biased: but, in this game, the jack is biased. This question of bias is interesting. In the early days of the game, bowls

were little, if at all, biased. Then bias was given by weighting with lead. Now, the bias is achieved by turning one side of the bowl less round than the other.

Players generally use two bowls each in a game, or four if playing singles, and the player or side with the best record of bowls near the jack wins the "end"—doubtful instances being accurately measured. An agreed number of ends make up the game, the side winning the most shots throughout the whole game being the winner. With a number of bowls all being played, and each being liable to a hit from a following player, it will be appreciated that there is a good deal more in Bowls than the mere rolling of a bowl, even a biased bowl, at a small white ball.

### BOXING.

The sport of boxing, sometimes called "The Noble Art of Self Defence," though actually aggression is its keynote and defence an incidental, has a long history, for it is a modern continuation of the old sport of Prize-Fighting.

Prize-Fighting was very popular at the time of the Regency, and it retained this popularity—though illegal and always subject to interference by the authorities—right up to the end of the nineteenth century, when it was succeeded by the present-day glove-fighting or boxing. A prize-fight was a very rugged, not to say brutal, affair. Bare fists were used, and wrestling holds and throws were allowed under the London Prize-Ring Rules, which governed the contests. All fights were to a finish, and a round ended when one of the contestants went down. When this happened, the fighter had 30 seconds, during which he received attention from his seconds or "bottle-holders," to come up to "scratch." It was when a man failed to do this that a fight finished.

Prize-fighting was illegal, and, in this, its position was clearer than is that of boxing to-day. Though not actually illegal, it is certain that boxing, in the sense that it is in actual fact an attempt on the part of two men to knock each other unconscious, is not legal. If there is no knock-out, however, a decision on points is given, and, technically, boxing is a contest of skill for points, the knock-out not being recognised in the official rules. At any rate, properly regulated contests are not now subject to police interference.

Boxing differs from prize-fighting in many respects. First, gloves are worn, and clean hitting only is allowed, holding and throwing as in wrestling being forbidden. Rounds are subject to a time-limit, usually three minutes, and they end after that time, even if both men are still on their feet, as, of course, they generally are. There is a one-minute interval between rounds. As these timed rounds do not end simply because a man goes down, a fallen contestant has ten seconds, counted off aloud by the referee, in which to rise; and it is when he fails to do so that the legally unofficial but practically conclusive knock-out occurs. Should the round end while he is on the floor, then, of course, the fighter has the normal minute interval, during which he may receive attention, in which to recover. The referee may stop the bout at any time if he thinks that a man might suffer serious injury if allowed to continue; and, in this case, the winner is credited with a "technical knock-out"; as he is if his opponent fails to come up when the bell sounds to start a round. In the early days of glove-fighting, fights were to a finish, as in the prize-ring days. Rounds were limited to three minutes, but they were not limited in number. Later on, it became the custom to limit a fight to so many rounds, a points decision being given if there was no knock-out. Fifteen rounds is the limit at the present time.

Boxers, breaking the rules by hitting below the belt or by some other infringement are usually warned once or twice, after which they are disqualified. In the United States, the "no foul" rule operates to prevent disqualifications. The authorities make it a rule for fighters to wear certain protective equipment, and, under these circumstances it is maintained that a foul blow would not actually incapacitate a man. If a foul blow is delivered, the man responsible scores no points at all for that round, and his opponent has five minutes in which to recuperate. There has been some talk about introducing this rule into

Britain, but this has not yet been done, although a recent regulation compels boxers to wear the same protection as is used in America—and which consists of a device invented by an Englishman.

In professional boxing the referee is solely responsible for any points decision. In amateur contests judges give the decisions, the referee voting only if a casting vote is necessary. Amateur bouts are usually limited to three rounds, as the contestants may be required to fight several times during a tournament. In Britain the count following a knock-down in an amateur contest is silent.

The difference between a good professional and a good amateur is probably more marked in boxing than in any other sport. Amateur boxing, incidentally, is the only sport in which the whole of Europe, including Britain, combines to select a team to oppose the United States.

Boxing contests, both professional and amateur, are arranged in classes according to body-weight. The normal divisions are: flyweight, up to 8 stone; bantam-weight, up to 8 stone 6 lb.; feather-weight, up to 9 stone; light-weight, up to 9 stone 9 lb.; welter-weight, up to 10 stone 7 lb.; middle-weight, up to 11 stone 6 lb.; light-heavy-weight, or cruiser weight, up to 12 stone 7 lb.; and heavy-weight, any weight. Amateurs have two additional classes, light-welter-weight, up to 10 stone, and light-middle-weight, up to 11 stone.

Prize-Fighting was governed successively by "Broughton's Code," the "New Rules of the Ring," and the "London Rules." Then, in 1866, the eighth Marquess of Queensberry drafted the rules that have been the basis of boxing ever since. Professional boxing in Britain has been controlled since 1929 by the British Boxing Board of Control. The Amateur Boxing Association has ruled amateur boxing since 1884, when it succeeded the Amateur Athletic Club, which had looked after both boxing and athletics.

### CRICKET.

Cricket can claim a longer history than any other team game. Historians have attempted to trace its origin in various ball games played by ancient races, and, even if some of these derivations are a little far-fetched, we can at least say that 250 years ago the game was being played in a form not so very dissimilar from that of to-day. Hampshire, particularly the village of Hambledon, Surrey and Kent really pioneered this game that was later to be taken so seriously at the other end of England, though the great days of the Hambledon cricketers were somewhat later than our late seventeenth-century starting point.

Cricket to-day is played by two teams, each consisting of eleven players, which take it in turn to "bat" and to "field." It is the object of the batting side to score "runs," and to score as many as possible before they are got "out" by the fielding side, who then take their turn with the bat. The ground is generally oval in shape, with a white line, called the "boundary" line, marked round it. The "wickets," which the batsmen have to defend, are pitched near the centre of the ground on a specially well-tended piece of turf, or on matting or concrete. There are two wickets, each consisting of three "stumps," joined across the top by two "balls." The wickets are pitched opposite each other 22 yards apart. The bats used have a flat striking surface, and the ball, which weighs about 5 ounces, is red in colour and hard.

The ball is delivered by "bowling," not throwing, it from one wicket to the batsman at the other, six balls—comprising one "over"—being bowled from each end in turn. The batting side bat two at a time, one at each end, so it follows that with eleven men in a team, the fielding side has to get ten out to finish the innings, as the remaining batsman then has no one to partner him. There are a number of ways in which the batsman can be got out. If the ball, passing the bat, hits the wicket, or if he plays the ball on to his wicket, he is out "bowled." If he hits the wicket with his bat when making a stroke, he is out "hit wicket." If he leaves his ground, misses the ball, and the wicket-keeper, having taken the ball after it passed the wicket, "breaks" the wicket, he is out "stumped." If he hits the ball and it is caught before it touches the ground, he is out "caught." If, when running, he fails to reach his ground before the wicket is broken, he is out "run out." If the

ball when bowled would have hit the wicket, but hits his leg instead, he is out "leg-before-wicket"—though this is a very complicated rule, and there are occasions when, if the ball did not first pitch in line with the wicket, the batsman is not out, even though only his leg stopped it hitting the wicket. A batsman may also be given out if he obstructs any of the fieldsmen.

Runs are scored by the two batsmen running past each other from wicket to wicket while the ball is being retrieved after a hit. Naturally, the batsmen will run as many runs as possible for a hit, but if the ball crosses the boundary line it automatically counts four, or, if it does so without touching the ground, six. Certain runs, called "extras," can be scored without the ball being hit. If the ball passes the bat without hitting the wicket and goes far enough for a run, this is counted as a "bye." If it goes off the batsman's leg, not having been kicked away deliberately, and they run, it is a leg-bye. If it is bowled so wide of the wicket that the batsman cannot reach it, it is a "wide," and one run is added to the score. If the bowler comes in front of the wicket at his end before delivering the ball, or if he throws it, it is a "no-ball." In this case, the umpire shouts "No-ball" as quickly as possible, and the batsman can then hit at it, counting any runs he scores, but not being out if he misses it or is caught. If he does not score off a no-ball, then one run is added as an extra. Wides and no-balls do not count as part of the over.

It is obvious that members of the fielding side will be disposed about the field in what are considered the best positions for preventing runs and for assisting in getting the batsmen out. One man, of course, is the bowler, and one other position is fixed. This is the wicket-keeper, who stands behind the batsman's wicket. The remaining nine positions are not fixed, but there are a large number of recognised positions: far too many, in fact, for them all to be occupied at once. Those which are occupied will depend on a decision reached by the bowler in consultation with his captain, and arrived at in the light of the particular type of bowling, and how the batsman is likely to deal with it.

To gain some idea of the recognised positions, imagine a right-handed batsman standing ready at the wicket, his body at right angles to the line from wicket to wicket. The side of the field in front of him, nearer to his bat than to his body, and on the left of the bowler, is the "off" side. Behind him, nearer to his body than to his bat, and on the bowler's right, is the "leg" side. On the off, to the right of the wicket-keeper, behind the wicket and close to the bat are the "slips." There may be up to four of these, called, going from the wicket-keeper outwards, "first," "second," "third" and "fourth slip." Behind them, near the boundary, is "third man." Coming a little forward from the slips, but still behind the bat and close to it, is the "gully," where there may be two men. Level with the bat, in front of it and close to it, is "point," or, if he is standing farther back, "deep point." Coming farther forward, in front of the bat on the off, but not so far round as to be level with the bowler's wicket, is "cover," who may have a man some way behind him at "extra cover." About level with the bowler, or a little farther back, is "mid-off," with, possibly, a man behind him on the boundary at "long off." All these positions have their counterparts on the leg side. The leg equivalent of "long off" is "long on"; of "mid-off," "mid-on"; of "cover" and "extra cover," "mid-wicket" and "deep mid-wicket"; of "point" and "deep point," "square leg" and "deep square leg"; of "gully," "short leg"; of "third man," "long leg"; and of "slip," "leg slip."

First-class matches, i.e., international or "Test" matches and County Championship matches, last three days or longer, and are two-innings matches. Most club matches are restricted to one day or to half a day, and consist of one innings each. In a one-innings match, the side batting second need not continue its innings after the opponents' score has been passed, as the match is then considered won by so many wickets, i.e., the number out of the ten which have not been captured. The same applies, of course, during the second innings of a two-innings match. Should the side batting first prove the winners, it wins by so many runs, i.e.,

those scored in excess of the opponents' final total. In a two-innings match, the innings are alternate, i.e., the side which bats first also bats third: but there is an exception to this rule. Should the side batting first get its opponents out while they are still 150 or more runs behind, then the side which is ahead can, if it wishes, require the other side to bat again at once, the leading side keeping its second innings in reserve to be used if necessary. If a batting side thinks that it has scored sufficient runs, and that, if it continues to bat, time will be up before the other side has been got out, it can declare its innings closed. In this case, should the other side get the necessary runs, it wins, of course, even though it may have lost more wickets than had the other side by the time of the declaration.

Although cricket quickly spread over England and became known as "England's National Game," its story outside England has been a peculiar one. Even as close at hand as Scotland and Ireland, it has never been taken up very seriously or with much enthusiasm; and the Continental countries which have adopted so many English games have, with one exception, left cricket severely alone. The exception is Holland, where the game is played enthusiastically, the standard of the best players being about equal to that of good English club cricketers. Cricket is played in the United States and Canada, but only to a slight extent, and then, particularly in the United States, chiefly by Englishmen. Apart from Canada, however, the Commonwealth countries have been enthusiastic. The standard in Australia is almost certainly the highest in the world; and South Africa, New Zealand, the West Indies, India, and Pakistan can all turn out teams capable of holding their own with England.

Cricket has its disadvantages. It does not offer a speed-loving era a great deal of action; it is utterly dependent on fine weather; and many games have to be left inconclusively drawn. Its retention of the title of England's National Game is now more of a courtesy than an indication of fact; but cricket's place in the scheme of things sporting seems secure enough. There are many people who, despite frequent suggestions for "brightening up" the game, are perfectly satisfied with it exactly as it is.

### CROQUET.

Croquet has been played in Britain for almost exactly a century, having come to this country from France. The governing body, the All-England Croquet Club, was founded in 1868, with headquarters at Wimbledon. This fact is important, because, not long afterwards, Wimbledon also became the headquarters of Lawn Tennis, and it seems likely that the very rapid growth in the popularity of this game was a factor that may have restricted the development of Croquet. Croquet retained, and still retains, its following, however; and, in addition to championships and tournaments, it is widely played on the lawns of private houses.

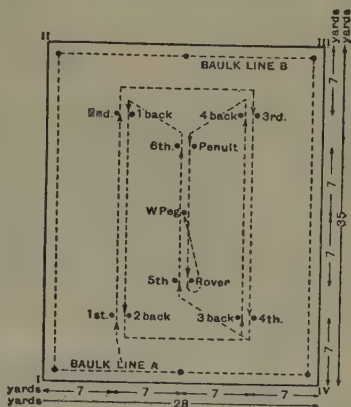

The equipment consists of four balls, coloured blue, black, yellow, and red; four mallets usually also marked blue, black, yellow, and red on the handles; six hoops; and a peg. The standard size of the lawn is 35 yards by 28 yards, but a smaller lawn can be used, provided that length and width are in the proportion of 5 to 4.

The hoops, which stand 1 foot out of the ground, and the peg are set out as shown in the diagram, the peg being exactly in the centre of the lawn. Usually two players, taking the blue and black balls, oppose two using the yellow and red, though singles may be played. In this case, each player has two balls, one using blue and black and the other yellow and red. Each player must pass his ball through the hoops, going round the circuit twice in the order illustrated, and finishing by hitting the peg, or "pegging out." Balls must pass through each hoop from the front. Each side, though not necessarily each ball of each side, plays in turn. Full points for a completed round are 26, and, to win, a side must finish both its balls before the other side does so.

There is a good deal of scope for skill and tactics in Croquet, as players may earn extra turns, or the right to try to "make a break," in various ways, such as hitting another ball with their own or

passing through, or "running," a hoop. It is also sometimes expeditious to play a shot designed to increase the other side's difficulties, rather than simply to advance one's own course round the circuit. While endeavouring to score his own

### STANDARD SETTING.

Only those portions indicated by a continuous line need be marked on the court.

The order of making the points is indicated by the arrows.

points, a player will also be considering ways and means of leaving his opponents at a disadvantage.

There is a system by which handicap matches may be arranged, a certain number of extra turns, or "bisques," being given to one player. A "half-bisque" is an extra turn in which no hoop may be scored.

### CYCLING.

Few inventions can have been so widely adopted so rapidly as the bicycle. This is not surprising, for this comparatively simple method of transportation offers many advantages, with few counterbalancing disadvantages, in all of the three main activities for which it is used—cycling for utilitarian purposes, cycling for recreation, and cycling as a competitive sport.

Utilitarian cycling includes using a bicycle for "going to and from work, for going shopping, and for every fairly short journey that has to be undertaken. One advantage is that a limited amount of luggage can be carried; and another is that, like walking, it offers some exercise, but it enables the traveller to cover the ground three or four times as fast as when walking. It makes one independent of local bus and train services, and yet, in towns, it is probably as fast as the public transport. A bicycle is not a very expensive item; it should last for many years; and it should soon save its cost in fares and in shoe-leather.

It is also ideal from a recreational point of view, for the touring cyclist enjoys most of the advantages of either the walker or the motorist, while avoiding their disadvantages. The walker gets plenty of exercise and a splendid view of the country, but the distance he can cover is very limited. The motorist gets plenty of distance, but at too fast a pace to see the country, and he gets no exercise. The cyclist, however, gets exercise, while moving fast enough to cover four times the ground seen by the walker, yet not so fast that he cannot see the country through which he is passing.

Cycling as a competitive sport is a vast subject, for no other sport in which most of the competition takes the form of racing offers so many different types of racing. A cycle-racing meeting provides, not only first-class sport, but also a wide variety of sports. On the Continent, the popularity of

cycling far exceeds that of any other sport, and the leading riders are the objects of tremendous hero-worship. The sport also has a large following in Britain, and a growing one, which would grow even faster if there were more tracks available for top-class meetings.

Cycle racing takes place on banked tracks like motor racing tracks, on flat grass tracks, on cinder tracks, on indoor board tracks, and on roads. There are races at all distances from short sprints to the Tour de France, which lasts for a month. The sport includes ordinary straightforward massed-start races; short-distance championships in which the competitors are drawn against each other in pairs, the winners going on to the next round, and so to the final; time trials, in which each rider completes the course separately against the clock; point-to-point races, in which the first three at the end of each lap score points, and the rider with the most points is the winner, even if he does not actually finish first; courses des primes, in which the leader at every lap wins a prize; motor-paced races, in which each rider races behind a motor-cycle, which has a large windscreen and a small roller at the back, right on to which the cyclist rides; pursuit races, in which the riders start spaced out round the track and try to catch each other, anyone so caught being eliminated; Madison races, in which teams of two race, with one man actually on the track and his team-mate relieving him at will (this is the system used in the six-day races); and tandem races.

There is also cycle roller racing, in which the cycles are on sets of rollers. The riders do not actually move forward at all, but the distance they cover is automatically registered on large dials. Then there is the latest form of cycle racing, cycle speedway. This is a sport devised by youths, who started it simply by trying to imitate the motor cycle speedway riders by holding cycle races on pieces of waste ground. They raced as the speedway riders do, one pair opposing another pair, and with all the races at the same distance. This informal activity spread like wild-fire, and, in an amazingly short time, another properly organised sport had arrived. The National Cyclists Union, the governing body of cycle racing in Britain, then acted most sensibly. Realising that these youngsters had started this sport out of admiration for speedway racing, into which they might well gravitate in the course of time, the cycling rulers took over the organisation of this new sport in the hope that they might be able to persuade these youths to come into cycling instead.

Cycle racing is both amateur and professional, and both types of rider may appear at the same meeting. There are not many professionals in Britain, but, as far as this side of the sport does exist here, the N.C.U. governs it as well as the amateur racing. The N.C.U. also has a touring side, though this is not, perhaps, as well known as the activities of the Cyclists Touring Club, which concentrates entirely on touring. This is a tremendous organisation, on the working of which, it is interesting to note, the methods of the Automobile Association were based—for the C.T.C. came first by many years. Another cycle racing body is the British League of Racing Cyclists. This organisation is in rivalry to the N.C.U., and B.L.R.C. cyclists are not recognised as amateurs by the N.C.U., nor for the purposes of such competitions as the Olympic Games. The main point of difference between the N.C.U. and the B.L.R.C. is massed-start road racing. This is extremely popular on the Continent, where everything stops for it, and where roads are specially closed. In Britain, however, roads are not closed for racing, and the N.C.U. will not permit massed-start racing, except on closed circuits such as parks, most road races being time trials, which take place very early in the morning. The B.L.R.C. does organise massed-start road races, the riders being subject to certain rules such as "No overtaking in towns," etc.

Finally, it would be surprising if no team game involving the use of cycles had been invented; and in fact, there is such a game. This is bicycle polo, which has its own governing body, the Bicycle Polo Association. This is a dangerous game, involving hard wear on men and machines, and requiring great cycling skill and considerable nerve. It is very popular, and there are international matches between the home countries

## FENCING.

Fencing can claim a longer history than most competitive sports, for it is, of course, the present-day equivalent of the old custom of duelling; and, like some other very ancient recreations—Archery, for instance—it is fast growing in popularity, and has shown an extraordinarily rapid development during the last few years.

As far as Britain is concerned, the earliest form of duel with which most of us come in contact through reading is the clash of mounted knights armed with lances in the mediæval Tournaments; and it is interesting to note that this was not confined to occasions when the protagonists were out to kill or seriously disable each other, but was often a purely sporting affair in which special less-lethal lances were used. In later times, duelling became dismounted and the weapons changed. In Elizabethan days, duellists fought with a sword, for attacking thrusts, in the right hand and a dagger, for defensive parries, in the left; a very highly skilled form of swordsmanship which can still be seen demonstrated occasionally in such displays as the Royal Tournament. Later still, the dagger was discarded, and duels were fought as are the fencing bouts of to-day with only the one weapon, the sword, for both attack and defence.

Duelling began to decline in Britain during the Regency period, though the gentlemen of those days continued to learn swordsmanship, and to fence with the practice weapon, the foil. At that time, however, it became fashionable for young men of aristocratic upbringing to learn how to use their fists for fighting, and it was a proud boast in any circle to be able to say that you could hold your own with a professional pugilist. Thus was born the "good old English" method of settling disputes with the fists, and duelling was relegated more and more to the ranks of purely "foreign" customs. Though actual duelling is now illegal almost, if not quite, throughout the world, it is still carried on occasionally on the Continent. Even before the cult of fist-fighting came into being, the art of swordsmanship had made most of its advances on the Continent, rather than in Britain, France and Italy being the nations most prominent in its development. To-day, the fencers of these and other Continental countries are still the best in the world, and, though countries like Britain and the United States are taking more and more interest in the sport, the international teams of those countries at the present time rely to a large extent on fencers of Continental European descent.

The right to duel in olden times was restricted to "Gentlemen." Only Knights fought in mediæval Tournaments, and only men of aristocratic birth duelled in Elizabethan times and later; and something of this restricted atmosphere pervaded the early days of fencing as a modern sport. Not that embryo fencers' antecedents were subjected to investigation, but clubs were few and expensive and rather exclusive. In more recent times, however, things have changed, and class tuition in fencing has opened a first-rate sport to anyone who wishes to take part in it. Fencing classes have long been a part of the curriculum at dramatic academies, and they are now included by some educational authorities in their programmes of adult evening classes. Almost invariably more students wish to enroll than can be accommodated, and the number of fencers almost doubled in the year which followed the 1948 Olympic Games. Fencing is regularly included in the Olympic Games, and there are many other championships, international contests, and competitions as well.

Modern competitive fencing offers contests with three different weapons: the foil, which, formerly merely a practice weapon, is now the only weapon with which women fence; the epee, the real duelling-sword; and the sabre, with which hits are scored by cutting with the blade, as well as by thrusting with the point. All the terms used in fencing are in French, and many of these, describing classic cuts, thrusts, and parries, are traditional. Fencing is a sport which must be learned by personal tuition, either in private or in class, and which cannot be picked up from books.

Some special equipment is required. The weapons, of course, have "buttons" on the points, but these can come off, and fencers wear a special glove on the sword hand, a padded jacket, and a

mask. Even so, accidents happen, and it is extremely foolhardy to attempt even the lightest practice without this equipment. Actual fatalities not only can happen, but have happened through fencers practising without masks. An exceedingly dangerous habit which should be avoided at all times, but which is not always avoided even by top-class fencers, is the whipping off of the mask to claim a hit before the officials have stopped the bout. Many fencers do this. They think they have hit, so they immediately shout out and whip off the mask. The opponent may be in the very act of thrusting or cutting as they do so, and no accident caused in this way puts any blame on anyone except the injured person.

The fact noted above that fencing is a regular subject at dramatic academies hints at one of its assets. It will do much to inculcate grace of movement and lightness of foot. It requires considerable agility, strength of wrist and forearm, good eyesight, and quick mental reactions—and it will, of course, help to develop all these qualities, including eyesight, which can be improved through eye exercise. Incidentally, people whose eyesight is below normal, except with glasses, are not debarred from fencing. As masks are worn, it is perfectly practicable to fence wearing glasses, and, in fact, several of the world's leading fencers do so.

not surprising that these early discussions took place at the Universities—particularly, as a matter of fact, at Cambridge—as it was there that boys from all the schools met just after leaving school.

It soon became apparent that there was no reconciling those who wished to permit handling of the ball and those who opposed this, so the two schools of thought agreed to differ, and to go their separate ways. So, right from the outset, there were to be at least two kinds of football. It was the non-handlers who went ahead the faster, and whose game was to spread to almost every country in the world.

### Association Football.

Those whose idea of football was that it should be a kicking, and not a handling, game worked out their rules, and, in 1863, the Football Association was formed to govern the game. It was from the name of this body that the game took the name of Association Football, or, as it is more widely known, especially outside Britain, Soccer.

Soccer is played with a round, leather-covered ball weighing from 14 to 16 ounces and with a circumference of from 27 to 28 inches, on a pitch marked out as in the accompanying diagram. A team consists of eleven players, the positions being

### FOOTBALL.

If the growth and popularity of sport during the twentieth century has been remarkable, hardly less remarkable is the huge proportion of that sport which takes the form of one kind of football or another. There are seven different games of football now widely played, and one of them, Association football, is almost certainly the most popular sport in the world. It is interesting to note that this is the only kind of football in which handling of the ball is not permitted.

It is impossible to say just who first thought of football. Attempts have been made to trace the game back to the Romans; and it is certain that some form of the game made a very early appearance in Britain, for it was one of several sports legislated against in favour of archery. This early football, however, took the form of struggles between whole villages, whose citizens used to oppose each other *en masse*, and play over a cross-country course of several miles. People past whose houses the battle was likely to rage barred and shuttered all doors and windows, and, altogether, the performance bore little resemblance to anything we know as football to-day.

The direct ancestors of present-day football were the games played at English public schools a century and more ago. Several schools played football, but all the games differed, the rules often depending on purely local considerations regarding the available space. These games were popular, and it was almost inevitable that, sooner or later, old boys of these schools should try to work out a set of rules that could apply universally. It was

goalkeeper, right and left backs, right, centre, and left half-backs, and the five forwards—outside-right, inside-right, centre-forward, inside-left, and outside-left. The object of the game is to score goals by putting the ball between the goal-posts and under the cross-bar which is 8 feet high. The ball is advanced by kicking or heading it, and it must not be handled, except by the goalkeeper, who may catch, punch or throw it when in his own penalty area, but who may not run with it. A game lasts for 90 minutes, divided into two 45-minute halves with an interval of not more than 5 minutes between them. The teams toss for choice of ends or for kick-off, the side which does not kick-off at the start doing so after the interval, at which ends are changed.

The game is started by a player kicking the ball from the centre of the field. It must travel at least its own circumference into the opponents' half, and the kicker must not play it a second time until someone else has done so. The opponents must remain outside the centre circle and in their own half until the ball has been kicked. The game is restarted in this way after a goal has been scored, being kicked-off by the side against which the goal was scored.

If the ball goes over the touch-line, it is thrown in by a player of the side which did not put it out, the thrower using both hands. If it is kicked over the goal-line wide of the goal by the attacking side, it is kicked-off by a defender from the 6-yards line. If it is sent over the goal-line by a defender, the attacking side kick it in from the intersection of the goal- and touch-lines. Free kicks are given for infringements, these being either "direct" or

"Indirect," Direct kicks, from which a goal may be scored, are for deliberate infringements; indirect, from which a goal cannot be scored, for more technical offences. For an offence by a defender in the penalty area, a penalty shot is awarded, this being taken from the penalty spot with no player, apart from the kicker and the goalkeeper, who must not move until the ball has been kicked, within 10 yards. For certain offences in the penalty area, however, such as "carrying by the goalkeeper" and "obstruction," an indirect kick is given.

A player is "offside" if he is nearer his opponents' goal-line than is the ball, unless there are two opponents between him and the goal-line, or unless the ball was last touched by an opponent. He cannot, however, be offside in his own half, nor from a throw-in. If a player in an offside position interferes with the game, a free kick is awarded against him.

The main objects of Rugby are the scoring of "tries" and the kicking of goals. Tries are scored by touching the ball—which is oval in shape—down behind the opponents' goal-line but in front of the dead-ball line. Goals are scored by kicking the ball between the goal-posts but over the cross-bar. The game is started by a kick-off, and the ball may be advanced by kicking or carrying it. It may also be passed by hand, but it must not be thrown or knocked forward. Players in possession may be tackled by being caught hold of and thrown down, but they must not be tripped. They may ward off tacklers by pushing out their hands, with the fists unclenched, towards them. When a player is tackled in possession, the ball must next be played with the foot. A frequent method of restarting the game after a stoppage is the "scrummage." In this, certain players—from six to eight of each side—bend down and push against each other, the first

#### NOTES:—

Goal dimensions.—10 feet is taken from the ground to the top edge of the crossbar and 18 feet 6 inches from inside to inside of the goal posts.

Soccer is easily the most popular game in Britain. In England alone there are ninety-two major professional clubs with some 2,750 professional players, apart from countless amateur clubs of all standards. There are innumerable Cup and League competitions, and the F.A. Challenge Cup competition is one of the best-known annual sporting events in the world. This attracts well over 600 clubs each year. Officially a winter game, the Soccer season runs from August until May—and, in Scotland, even the short summer months are filled in with five-a-side tournaments. The game is extraordinarily popular all over Europe and in South America, and it is played to some extent in the United States, Canada, Australia, and South Africa. It is included in the Olympic Games, and there is a periodical tournament for the Championship of the World, open to the best team, professional or amateur, that any country can produce.

#### Rugby Union and Rugby League.

The first organised handling game of football was based on the game played at Rugby School, and it took this name, the governing body being called the Rugby Union. Within twenty-five years of its beginning, however, there were two distinct versions of Rugby.

Played on a pitch marked out as in the diagram,

row of each side consisting of three players and the remaining "scrummagers" forming two subsequent rows. The ball is then put into the tunnel between the front rows, who endeavour to hook the ball back through their scrum with a view to putting their team-mates in possession for a passing or running movement.

The division into two separate games came in 1895, when there was a dispute on the question of legalising payment for time lost from work by players. The Union would not agree to this, so twenty-two clubs, mainly in Yorkshire, seceded and formed a new independent governing body, first called the Northern Union, but now called the Rugby League. At first, both bodies were controlling the same game, but as each has made various rule changes during the last fifty years quite independently of the other, the games, though still basically similar, now do contain certain marked and important differences.

The foregoing brief description of the game applies to both codes, but, beyond that, there are two versions of almost every regulation. To start with, the number of players in a team is not the same in the two games. Rugby was originally played twenty-a-side, but this was reduced to fifteen, and this was the number at the secession. It is still fifteen in R.U., but, in R.L., it is now thirteen—the positions being seven backs and eight forwards in R.U. and seven backs and six

forwards in R.L. Scoring is also different, though the basic score, the try, counts three points in either game. Four kinds of goal are possible in R.U., these being a goal scored by a place-kick from an attempt which is awarded following a try, a goal scored by a drop-kick during play, a goal scored by a place-kick or a drop-kick when a free kick has been awarded, and a goal scored by a drop-kick when a player has made and claimed a "mark" or "fair catch," i.e., when he has caught the ball and simultaneously driven his heel into the ground and called "Mark." The goal after a try counts two, and any other goal three. In R.L., any of these goals is permitted, except the goal from the mark. Marks are allowed, but goals cannot be kicked from them. Any kind of goal counts two.

There are several differences in actual play. In R.U., the ball may be kicked out of play, and it is then put in again level with the place where it crossed the line. In R.L., direct kicking out is allowed only from a free kick. If the ball goes out without first bouncing in the field of play from any other kick, it is put into play at the place where it was kicked. In R.U., the ball is put back into play after it has crossed the touch-line, either by a throw-in or by a scrummage, as may be decided by the side which did not put it out. In R.L., it is always a scrummage. Incidentally, whereas in R.U. the ball is put into the scrummage by a player of the side not considered responsible for the stoppage, in R.L. it always put in by a member of the defending side. Also, in R.L., a player tackled in possession must be allowed to get up and play the ball, a privilege not accorded him in R.U.

The total effect of these variations is that R.L. is a faster and more open game than R.U. Fewer forwards mean less "spoiling" and more passing and running among the backs; the rule against kicking out keeps the ball in play much more; and the rule by which tackled players must be given room to get up prevents loose "mauling" and keeps the ball in view. A Rugby game under either set of rules lasts for 80 minutes, divided into two 40-minute halves.

In addition to Britain, both types of Rugby are played in France, Australia, and New Zealand, and the Union game is also played in South Africa. There are isolated outposts in some other countries as well. Both games are primarily amateur, the Union game entirely so, and the League game to the extent that, while there are well over 800 amateur clubs, there are fewer than thirty professional clubs, and these are almost entirely part-time.

#### Other Codes.

Other forms of football, all of which permit handling, are American, Canadian, Australian, and Gaelic football.

American football is played eleven-aside on a pitch marked by a line across it every 5 yards; and with a ball and goals, which resemble those used in Rugby. Scoring is by "touchdowns," which are like tries, but which count six; conversions after touchdowns, which count 1; field goals scored during play, which count three; and "safeties," which means that, if the defending side carry the ball across their own goal-line and there touch it down, two points are awarded to the attacking side. The ball is advanced by carrying it, passing it—and it may be passed forward—and kicking it. The game consists of a series of "plays" or "downs," the ball becoming dead as soon as the ball-carrier, when tackled, touches the ground with his hand or his knee. A team must advance 10 yards in four downs or give up the ball to the other side. Players are allowed to run ahead of the ball-carrier to protect him from tacklers by "blocking" them out of the play with their shoulders. Penalties take the form of distance, usually 5 or 15 yards, lost. A game lasts 60 minutes, divided into four 15-minute quarters. Canadian football resembles American, but is twelve-aside, uses only three downs, and limits blocking. Touchdowns count five.

Australian football is a fast open game played eighteen-aside on large oval grounds, there being no offside rule and high scoring in goals and behinds (i.e., near misses) being common. It is played to the practical exclusion of all other forms of football in the southern half of Australia.

In addition to the widely known Rugby game, several other school games are still played at the schools which invented them. Eton has the Field game and the Wall game. Harrow the Base game, and Winchester the Net game.

#### GAELIC GAMES.

The term "Gaelic Games" is usually taken to mean hurling and the particular brand of football called Gaelic football. They are, of course, Irish games, and they are seldom, if ever, played by people of any other nationality. They are, however, played regularly outside Ireland, for exiled Irishmen have formed Associations to organise them in several parts of the world. In England they are played in London, Warwickshire, Lancashire, and the East Midlands; and there are active centres in New York, Boston, and San Francisco, and in Australia and South Africa. In some Celtic centres, such as Wales, Cornwall, Devon, and the Isle of Man, the games have died out, but a form of hurling, known as shinty and with slightly different rules, is preserved in Scotland. Hurling is of very great antiquity, and English authorities in Ireland first tried to suppress it six hundred years ago. The game was kept alive, however, and it is still very much alive to-day.

To make a comparison with more widely known games, hurling could be called the Irish brand of hockey, while Gaelic football is, of course, an Irish equivalent of Association football—though it is, as a matter of fact, a blend of Association and Rugby football.

Hurling is played by teams of fifteen-aside, and it is said by some people to be the fastest game, using a ball, in the world. The ball and sticks, or, more correctly, the "slitter" and "hurleys," bear some resemblance to hockey balls and sticks, but nothing like hockey's "sticks" rule applies. The ball may be hit at any height and with either side of the hurley; and it can also be kicked or caught, though it must not be carried more than three steps nor picked up off the ground. There is a good deal of hard bodily contact, and it is one of the toughest games in the world. Despite this, the goalkeeper wears no protective padding, though he does have a larger hurley. Injured players may be replaced by substitutes. Certain things are prohibited, of course, and it is a foul to push, trip, kick, catch, hold, jump at, or butt an opponent, or to charge him from behind. Hurleys must not be thrown under any circumstances. There is no offside, apart from the fact that attacking players must not enter the parallelogram marked out near the goal ahead of the slitter. Scoring is by goals—between the posts and under the bar—or points—over the bar but between the posts projected.

Gaelic football, which is also fifteen-aside, is decided by goals and points in exactly the same way. The goals are similar to those used in both Association and Rugby games. They have the uprights and cross-bar with the nets behind them, exactly as in Association, but the uprights extend above the crossbar, as in Rugby. One goal equals three points. The ball used is round, and it may be kicked or caught. It may not be thrown forward, nor may it be carried, though a player may retain possession of it by dribbling, as in basketball, by bouncing it and re-catching it. This, too, is a very fast game, probably simpler in its essentials than any other kind of football. Bodily contact is frequent and violent, and substitutes are permitted in case of injury.

To Irishmen, these games, which attract crowds of 70,000 spectators, are symbols of nationalism and patriotism. Rule 24 of the Gaelic Athletic Association, which is nearly three-quarters-of-a-century old, states: "Any member who plays or encourages Rugby, Association football, Hockey or Cricket by that very fact incurs immediate suspension from membership of the Association." Despite this, quite a number of Irish Gaelic football players have subsequently made their mark in first-class English professional Association football.

#### GOLF.

Golf, a game of great antiquity and of Scottish origin, is widely popular in many countries, and extraordinarily so in Britain and the United States. Briefly, it consists of using certain clubs

with which to play a small, hard, white ball over a cross-country course of eighteen holes. The course will be several miles in length, and each hole will be several hundred yards long. Each hole has its fixed starting point and ends with an actual hole in the ground, the object of the game being to play each hole, and eventually the entire course, in as few strokes as possible.

The playing of each hole will fall into three sections, the initial drive, the approach, and the green. The starting point will be a flat piece of ground, raised slightly above the surrounding earth; and, on this, the player will "tee up" his ball on a small rubber "tee," which he will carry round with him, or, perhaps, on a small mound of sand. He will then hit the ball as far as he can towards the hole, distance being his main object at this stage. The stretch from the "tee" to the hole will consist of fairly smooth ground—the "fairway"—not necessarily devoid of hills and rises and containing, perhaps, a few trees. It will also probably contain a few "bunkers" or sand traps. The "fairway" will not, of course, be of indefinite width, and the ground at each side of it—the "rough"—will probably be just that: rough, consisting, possibly, of long grass, shrubs, or even a wood or a road. The player finds his ball, and plays one or more additional shots towards the hole, his play at this stage being dictated more by a desire to achieve accuracy of direction than by considerations of distance alone. The hole itself will be set on the "green": a rough circle of exceptionally well-tended grass. The hole, which has a tin cup in it, is marked by a flag, and it is this flag which will have been the player's target in the earlier stages of playing the hole. These flags, incidentally, vary in colour, but they are usually white or red, with, perhaps, one colour marking the first nine holes "out" and another for the second nine "home." Once on the "green," the third stage—"putting" for the hole—is played.

There are many different types of golf club, players being limited to fourteen. Those used for the actual drives will probably have wooden striking surfaces, while all the rest will have iron. The shafts of the clubs may be made either of wood or of steel. The latter are increasing in popularity, but they constitute something of a liability should the player be caught in a thunderstorm. These clubs formerly had rather attractive names, in some cases indicative of their functions, for instance, putter, loftier, cleek, niblick, mashie, even blaster—for use in deep sand traps. Nowadays, however, they are simply called the No. 1 iron, No. 2 iron, No. 3 iron, etc. Originally, most golf courses were by the sea, and these were called "links." To-day, this term is loosely applied to any course.

Obviously, the competitive side of the game lies in completing the holes and the course in fewer strokes than the other player; but there are actually two methods of play, match play and medal play. In match play, it is a question of holes. The player completing the first hole in the least number of strokes becomes 1 up. If the next hole costs the two players the same number of strokes—if in fact, it is "halved"—the first player remains 1 up. If the other player wins the third hole, the match is again "square"—and so on. Obviously, such a match will not continue after one player has become more holes "up" than there are still to play. If he becomes the same number of holes "up" as there are still to play, which means, of course, that he only needs to "halve" one hole to win, then he is said to be "dormy" so many. Medal play is stroke play. Regardless of any player's performance at any one hole, the important thing here is the number of strokes taken to complete the whole round. Medal play puts a greater strain on the player and demands a higher level of consistency than match play, for, in the latter, if he takes eight for a hole which he should do in three, he only loses the hole and will have plenty of opportunities to recover his position: while, in medal play, that eight goes down on his card and may be enough to ruin his score for the round. Also, in match play, a player may find his ball in a hopeless position from which it might take him a number of strokes to get out: so he just picks up his ball and gives up the one hole. In medal play, he must get out, counting all the strokes, for, if he picks up, he is out of the

competition from that moment. Incidentally, the player winning each hole, drives first from the next "tee"—in golf terms, he "has the honour." In the case of a "half," the "honour" remains with the player who last had it. While playing out the hole, the player farthest from it plays, even though he may be playing his third or fourth before the other player has played his second. This means that, in match play, "putting" on the "green" is always liable to be complicated by a fortuitously laid "stimpie," i.e., a player may be forced to "putt" with his opponent's ball standing between his own and the hole.

Every course has fixed sets of figures, one known as "bogey" and the other—a higher standard—called "par." These represent the performance that a first-rate player might achieve for a complete round. On them, the members of the particular club will be given handicaps, the handicap figure being the difference between their average round and that of the first-rate player. Possession of these handicaps, which can be altered on application supported by suitable evidence of a change in a player's standard—in either direction—enables golfers who are strangers to each other to arrange an even match. The handicap strokes are awarded, i.e., they are deducted from the actual performance, at certain holes according to the arrangements in force at any particular club.

A player must not receive any advice during a round, except from his "caddie," if he has one. The "caddie" is an attendant, sometimes a boy, but often a grown man, who makes a profession of carrying golfers' clubs round. They are often excellent golfers themselves, and they know their home courses inside out. Their assistance can be most valuable to a player new to the course; and their comments, either spoken or merely to be read in their faces, can be most disturbing to a player off his game. This rule about advice is one of the many laid down for golf by the governing body, the Royal and Ancient Club of St. Andrews. Other rules, called "local rules," apply at particular courses.

Not all golf matches are "singles" between two players. Championships are, of course, players being drawn against each other, and the winners passing on to the next round in match play championships, and going round in pairs in medal play championships: but matches between teams usually consist of both "singles" and "foursomes." In the latter, two players make up a side for the round, each playing his side's shots in turn. Players merely playing for pleasure sometimes play "threesomes," i.e., three players playing all against all, and sometimes "four-ball foursomes," i.e., four players, each playing his own ball. These rounds are bound to be slow, and such quartets should let players playing "singles" pass through them. Another form of match is the "best ball." The four players split up into two partnerships. All four players drive at each "tee," but, thereafter, each partnership carries on with only one ball—the best drive, of course—as in ordinary "foursomes."

Golf has a tremendous number of competitions, championships, and matches. Probably the four most important individual championships in the world are the British Open, the British Amateur, the United States Open, and the United States Amateur. American courses, incidentally, differ from those in Britain in the sense that they are generally more open with wider "fairways" and fewer obstacles. This makes for better scores, but not necessarily for a better game. The American ball is also slightly different, but the players of both countries seem well able to make the necessary adjustment in their play when visiting the other. In addition to a regular British entry for the American championships and vice versa, the two countries meet regularly in team matches for the Ryder Cup (professionals), the Walker Cup (amateurs), and the Curtis Cup (women). Britain also has a regular women's international match against France.

These big matches and tournaments are attracting more and more spectators nowadays; and one of the main problems which the golf authorities are going to have to solve in the near future is the handling of the huge crowds which want to see as much as possible of a game that does not lend itself readily to the convenient accommodating of anything like these numbers.

## HOCKEY.

Hockey as an organised game is about three-quarters of a century old. It was originally confined to Britain, but the rules varied slightly in each of the home countries. In 1900, the International Hockey Board was formed as the result of an agreement between the Hockey Association, the Irish Hockey Union, and the Welsh Hockey Association, with a view to the provision of a set of rules that could apply wherever the game was played. Two years later, Scotland joined the founder-members of the Board.

The game spread rapidly in Britain, but it was seldom played elsewhere, apart from India. There, it was taken up with terrific enthusiasm, and there is little doubt that Indian players are the best in the world. In more recent years, it has begun to win some popularity on the Continent of Europe, the Netherlands being amongst the first of these countries to take it up, and certainly the best of them. There is now a Federation Internationale de Hockey, and this has no fewer than twenty-three countries affiliated to it. In 1947, negotiations between this Federation and the British governing bodies resulted in the Federation becoming a constituent body of the International Board. The rules

goal is a net, with a board not more than 18 inches high at the foot of it. The striking circle consists of a line 4 yards long parallel to and 16 yards in front of the part of the goal-line between the goal-posts. This outer line is continued in each direction until it meets the goal-line by marking in quarter-circles with the goal-posts as centres. Flag-posts not less than 4 feet high should be placed at each corner of the ground, and at the centre and 25-yard lines, all those, except the actual corner flags being a yard outside the side line.

The ball used is white, and can either be sewn exactly as is a cricket ball or it can be seamless. It must not weigh less than 5½ ounces nor more than 5½; and its circumference must be not less than 8½ inches nor more than 9½. The rules actually state that a ball not conforming to these specifications may be used if the captains agree, but an official note to the rules mentions that this concession is intended to apply only to club matches.

Sticks have a flat striking surface on the left side only. Sticks with this reversed, which would be ideal for left-handed players, are not permitted. There must be no metal, no sharp edges, and no dangerous splinters on the head of the stick, and the whole stick must weigh not less than 12 ounces

GROUND.—100 yards by 55 to 60 yards. OPENING OF GOAL.—7 feet by 12 feet.

Diagram of Ground as marked out for Hockey.

approved by the Board should now, therefore, be uniform all over the world. Incidentally, the United States, which for long showed little interest in hockey, has now taken up the game.

The recent rapid interchange of various countries' particular games has resulted in, not exactly a change of name, but something approaching that for hockey. It is now often referred to as field hockey, to distinguish it from ice-hockey. Ice-hockey originated, of course, in Canada and it spread to the United States. As hockey on grass was not then played in those countries, the ice version was always referred to simply as hockey. Now that ice-hockey has won such popularity in Britain, there is a tendency even here to drop the word "ice," hence the possibility of confusion and the planting of the word "field" on the older game.

Hockey is played eleven-a-side, the usual composition of a team being goalkeeper, two backs, three half-backs, and five forwards, exactly as in Association football. A game consists of two thirty-five minute halves, unless a shorter time has been agreed upon by the two captains. Ends, decided in the first place by a toss, are changed at the interval, which must not exceed five minutes.

The pitch is a rectangle, 100 yards in length and not less than 55 nor more than 60 yards wide. This rectangle is marked with white lines, the longer ones being the side-lines and the shorter the goal-lines. There is also the centre-line and lines called the 25-yard lines midway between each goal-line and the centre-line. These 25-yard lines are not marked continuously, but in dashes as dotted lines. Parallel to the side-lines and 7 yards inside them are the 7-yard lines, which, like the 25-yard lines, are marked as dotted lines. The only other markings are the striking circles in front of the goals. The goals themselves consist of two perpendicular posts 4 yards apart, joined by a cross-bar 7 feet from the ground. Attached to each

and not more than 28 ounces. The handle must be able to be passed through a ring with an inside diameter of 2 inches.

No spikes and no nails are allowed on a player's boots.

The game is started and restarted after a goal or after half-time by a bully at the centre of the ground. The players bullying stand squarely facing the side-line, each with his own goal on his right. Each player taps the ground between the ball and his own goal-line and then his opponent's stick over the ball three times alternately, after which one of them must play the ball before it is "in play." At any bully, all the other players must stand nearer their own goal-line than is the ball until it is in play. No one apart from the two players bullying must be within 5 yards of the ball.

Only the flat striking surface of the stick may be used to play the ball, and no part of the stick may be raised above the shoulder either at the beginning or the end of a stroke. No ball moving above shoulder-height may be stopped with the stick. Umpires are empowered to penalise any hit which is dangerous, or which may lead to dangerous play. "Scooping" the ball or hitting it when it is in the air are permissible, but either may be penalised if the umpire thinks that the action in any particular instance is dangerous. Deliberate undercutting is not allowed. The ball must only be propelled with the stick, and it must not be stopped intentionally with any part of the body except the hand. If the hand is used, the ball must only be stopped. It cannot be caught and it must not be knocked forward. No hitting, hooking, holding, striking at, or interference with an opponent's stick is allowed; nor may a player obstruct an opponent by running between him and the ball, or by interposing himself or his stick as an obstruction. No charging, shoving, tripping, holding, kicking, or

striking at an opponent is allowed. Players must not tackle from the left unless they can play the ball without touching the opponent or his stick.

Goalkeepers, while in their circle, are exempt from some of these prohibitions. They may stop the ball with any part of their body, and they may kick it.

A goal is scored when the ball has passed over the goal-line between the posts and under the cross-bar, provided it was hit from inside the circle. If it is put through by a defender, it is still a goal to the attacking side.

There is an offside rule, which differs from that now used in Association football in that it is the same as the old offside rule in that game. To start with, no player may be offside in his own half. In his opponents' half, a player is offside when the ball is hit or rolled in by a team-mate unless there are three opponents between him and the goal-line, or unless whichever of his own team-mates is playing the ball is nearer the opponents' goal-line. Players who are offside are not penalised if they do not interfere with the play. A player in an offside position is put onside if an opponent plays the ball, but not, it should be carefully noted, if the ball merely touches or glances off an opponent.

If the ball crosses the side-line, it is rolled—not bounced or thrown—in by a player of the side which did not put it out. Whoever is rolling-in must stand with his hands, feet, and stick outside the field of play, and he must not again play the ball until some other player has done so. All the other players must have their feet and sticks inside the 7-yard line, though they may cross this as soon as the ball has left the roller's hand.

If the ball is sent over the goal-line, wide of the goal, by an attacker or, unintentionally, by a defender who is more than 25 yards from the goal-line, the restart is by a bully on the 25-yard line opposite to where the ball crossed the goal-line. If the ball is hit behind unintentionally by a defender who is within 25 yards of the goal-line, then a corner is awarded to the attacking side. If it is hit behind intentionally by a defender from any part of the ground, then a short or penalty corner is awarded.

A corner is a free hit from a point either on the goal-line or on the side-line within 3 yards of the corner flag. All the defending side must be behind the goal-line, and all the attackers outside the circle. When the corner hit comes into the circle, attacking players are not permitted to take a first time shot at goal. They must first stop the ball, or at least slow it down. A short or penalty corner is taken from a spot on the goal-line not closer to the nearest goal-post than 10 yards.

Penalties for infringements outside the circles usually take the form of a straight-forward free hit. Inside the circles, infringements by attacking players would still result in a free hit, but those by the defenders would be penalised by a short corner, unless the infringement has been an intentional one deliberately committed to prevent a goal, or, though unintentional, has, in fact, prevented a goal. In these cases, a penalty bully is awarded. Penalty corners or even penalty bullies can be awarded in extreme cases for defender's offences committed anywhere behind the 25-yard line, even though outside the circle.

The penalty bully is a two-man duel between the offender and a member of the attacking side. It takes place entirely in the circle, and all players, including the goalkeeper, if he is not the offender, must retire beyond the 25-yard line. The bully takes place 5 yards in front of the centre of the goal-line, and it continues either until the ball has been hit into the goal, in which case a goal is scored, or until it has been hit out of the circle by either player or over the goal-line wide of the goal by the attacker. If the defender hits it over the goal-line wide of the goal, the penalty bully is restarted. If the ball is cleared out of the circle or hit over the goal-line by the attacker, the game is restarted by a bully at the centre of the 25-yard line.

A hockey match should be controlled by two umpires, each of whom takes one half of the field and the whole of one side-line. If there is only one umpire, he should be assisted by two linesmen.

In the event of an injury, the umpire must stop the game. If, however, a goal has been scored before he stops it, it counts if he considers that it would still have been scored had the injury not

occurred. No substitutes for incapacitated players are permitted.

Hockey is entirely an amateur game. There are plenty of representative honours to be won in county, sub-divisional, divisional, and national sides, but there are no league competitions in British hockey—though there are in Northern Ireland—and no Cups, apart from a few special competitions such as the London Hospitals Cup. Almost every match is a friendly, though it is not less keenly contested on that account. Although it is a very fast game, players often continue playing it until quite an advanced age.

## KORFBALL.

As far as Britain is concerned, Korfball is the youngest of all team games. It has several features which have no parallel in any other game, perhaps the most unique being that it is a mixed game; not in the sense that it can be played by mixed teams of men and women, but in that it has to be. Teams consist of twelve players, six being men and six women. The game resembles Basketball in some ways, the goals, which are 11½ feet high, and the scoring of goals being similar. Korfball can be played on grass, asphalt, or any firm surface, and the pitch should measure 300 feet by 133 feet, though a smaller pitch can be used, provided that length and width are reduced in proportion. The playing area is divided into three sections, defence, centre, and attacking zones going forward down the pitch from either goal; and players do not move from one sector to another during the actual course of play. They do, however, have to be all-rounders able to play in any sector because of another unique rule, no parallel to which exists in any other game. This states that the players must change to another zone after every two goals. In addition to encouraging all-round play and preventing specialisation, this rule ensures that, even in a one-sided game, every player gets a fair share of the game. Four players from each team play in each zone, and players always mark opponents of their own sex. Running with the ball is not permitted, and it is advanced purely by passing. Players must not tackle or "check," and the ball can only pass from one team to the other by interception, either in the air or on the ground. Players may not score if there is an opponent within arm's length. A game lasts for 90 minutes, divided into two halves.

Though comparatively new to Britain, Korfball is not a new invention, as it was first played in Holland, the country of its birth, as long ago as 1902. There are now some 400 clubs, most of which run several teams, and a total of about 30,000 players in that country. The game spread to Belgium in 1927, but it did not reach a third country, England, until early 1947. When it did, it was immediately taken up with enthusiasm, and within two years there were about 1,000 players. The first English centres of the game were the Croydon district of Surrey and round Rotherham and Sheffield. Cambridge University soon took it up, and formed, not so much a club, as an Association composed of several clubs. There are over 100 players at the University. A British Korfball Association exists, and there is also an International Board made up of representatives of Holland, Belgium, and Britain. International inter-club games are already a regular feature of the game.

Korfball is really a winter game, and it is then that the various league competitions are played. It does actually continue, however, all the year round, for friendly social games, and the games between clubs from the three Korfball countries take place throughout the summer.

When one considers the many sports which are already firmly established in Britain, it is amazing that a new one should have progressed so rapidly. Its many attractive and original features, however, indicate that Korfball's rapid rise will continue for some time yet.

## LACROSSE.

Lacrosse, which originated from a game played by the Red Indians, was introduced into England from Canada in 1867. It has been played here ever since, the government of the game being in

the hands of the English Lacrosse Union, which works through the North and South of England Associations.

Basically it is, perhaps, the simplest of all field team games. The object is the scoring of goals by propelling the ball through with a crosse. This is made of wood, and it can be of any length, but must not exceed one foot in width at its widest part. The strings must be so woven that the ball cannot catch in the meshes, and there must be no metal on the crosse. The ball is a rubber one from 7½ to 8 inches in circumference, and weighing from 4½ to 5 ounces.

The goals, which consist of two uprights six feet apart with a cross-bar joining them at the top, are six feet in height. There are nets behind the goals, and these must provide a flat roof of netting from 9 inches to a foot in width behind the cross-bar. The distance between the goals is from 90 to 110 yards.

There is no touch-line in lacrosse, the boundaries of the pitch being the natural borders of the field, unless otherwise limited by agreement between the captains. Play can take place behind the goals, on some grounds for a considerable distance. All this makes the marking-out of the field very simple, as the only lines required are the centre circle, the goal-lines, and the goal-creases. The circle has a radius of 7½ yards from the centre point between the goals, and the goal-lines join each pair of uprights. With regard to the goal-crease, the present rules state that this is an oblong space 18 feet by 12 feet in front of, behind, and at each side of the goal-posts. Experiments are now being made, however, with a circular crease with a radius of 9 feet from the centre of the goal-line; and it seems likely that this will officially supersede the oblong within the next few years.

There are twelve players in a team as the game is played in England, though a reduction to ten became effective some years ago in Canada and the United States. The twelve positions from the goal forwards up the field are: goal, point, cover-point, third man, right and left defence, centre, right and left attack, third home, second home, and first home. Some of these terms are not used in Canada, the country of the game's origin. There, third man, left defence, and right defence were always known as first, second, and third defence, respectively; and right attack, left attack, and third home were called third, second, and first attack. It was one of these defence and one of these attack positions that were dropped when the sides were reduced to increase the speed of the game.

At the start, the players are spread right down the field, and are not all on their own side of the centre. There is no offside in lacrosse, except that no attacking player may enter the goal-crease before the ball, although players may run through the crease when chasing a ball which has gone wide. Should any player have to leave the field through injury, the other team must also withdraw a man. If, however, the injury was caused by a foul, for which the referee sends the offender off the field, then his team must withdraw another player during the absence of the injured man.

The game is controlled by a referee, whose decisions are absolutely final. He is assisted by two goal-judges. These are stationed one at each goal, and they do not change ends during a match. Their duty is simply to call "Goal" or "No goal" when the ball has passed through the goal according to whether or not it was scored fairly and legitimately. They give no reasons for their decisions, but they may, if they wish, consult the referee before giving a decision. They can assume an additional function by drawing the referee's attention to any player who may move after "Stand" has been called. The referee is directed to start and stop play by various calls, such as "Play," "Stand," "Face," "Draw," and "Time," but these calls may be replaced by the use of a whistle.

A game normally consists of four twenty-minute periods, but the captains may agree to play two forty-five-minute halves or otherwise to vary the length of the periods. Choice of goals is decided by a toss. Ends are changed at half-time and, if four periods are played, at quarter and three-quarter time as well. Intervals must not exceed ten minutes at half-time nor three minutes

at quarter and three-quarter time, though they may be of shorter duration.

The game is started or restarted after a stoppage by two players "facing." This means that the ball is placed on the ground between the backs of the two crosses, each player's crosse being between the ball and his own goal. On the word "Play," or at the whistle, they draw their crosses apart and towards themselves and the ball is then in play. It may then be advanced by running with it on the crosse, by throwing it from the crosse, or by kicking it. No goal, however, can be scored by a kick, except that, should a player kick it through his own goal, it counts as a goal for the other side. Should a foul be claimed, and then a goal is scored before the referee has stopped play, he may allow the foul and disallow the goal if an attacker is the offender. If a defender has committed the foul, the goal counts. No goal counts, however, if the referee had actually called "Stand" before the ball entered the goal. No player may handle the ball, except the goalkeeper, who, while not allowed to catch or throw it, may deflect it with his hand.

The "face" to start a period or after a goal has been scored takes place at the centre of the field, and no players except the two concerned are allowed into the circle until the ball has left it. With "faces" in other parts of the field, no third player may be within five yards. This method of restarting is used when the ball has crossed any agreed boundary line, the "face" taking place five yards inside the border; and if the game has to be stopped through the ball lodging in a player's clothing or in the goal netting. The ball must not be "faced" within ten yards of the goal if the stoppage has been caused by one of the attackers, nor within five yards of it at any time.

Once the referee has blown his whistle or called "Stand," to stop the game, no player may move until the ball is in play again, unless directed to do so by the referee.

Players are not allowed to charge opponents, apart from pushing them with the shoulder when trying to get the ball off the ground, nor may they push them with either hand or crosse, nor hold or trip them. They may, however, use the "body check," which simply means standing in the way of an opponent to impede him. This may only be done to a player who is actually in possession of the ball, or who is about to receive it, or who has just parted with it. "Crosse checking," which means charging into an opponent with both hands holding the crosse so that it hits the opponent's body, is strictly forbidden. An opponent's crosse may be checked with the crosse, but only if he has the ball or is about to receive it; and this check must not be a "slash" nor in any way unnecessarily violent. A check aimed at an opponent's crosse must be stopped, if possible, once the ball has been thrown. Interference with an opponent who is chasing anyone, or hindrance that takes the form of kneeling, crouching or falling in front of a player is illegal, as is falling on top of the ball to cover it. Players must not, of course, strike an opponent, nor even threaten to do so; and, needless to say, they must not throw their crosses. If a player drops his crosse, he may take no part in the game until he has regained it. Deliberate time-wasting by throwing the ball out of bounds or otherwise; constant appealing to the referee for a foul on trivial grounds; or wearing anything other than rubber-soled footwear are all offences, and are themselves treated as fouls.

There are no "free hits" in lacrosse. Generally speaking the game is restarted after a stoppage by two players "facing"; but, if a palpable foul has occurred and something stronger is required, the referee may send the offender off the field for the rest of the game, or for a shorter period, or he may award a "free position." When he does this, all the players must remain where they were when the game was stopped, except that the goalkeeper, if out of his goal, may return to it, and that no one must remain within five yards of the player to whom the "free position" is awarded. This player then takes the ball on his crosse, and, at the word "Play" or the whistle, the game continues. No "free position" may be given within ten yards of the goal-line, as measured direct from the line, not straight up the field, but to the point where the foul occurred. In an extreme case, the referee is empowered to order any player, including the

goalkeeper, away from any spot between the "free position" and the goal.

Lacrosse demands great speed and stamina, but, although a high level of skill demands much practice, it is not hard for a playing recruit or new spectator to pick up the main objects and to master the comparatively simple rules which govern it.

### RACKET GAMES.

One group of games which, through one or other of its component sports, can claim both great antiquity and great present-day popularity consists of the "Court" games, played with racquets and balls. There are at least eight games with a claim to inclusion in the group, these being Tennis, Lawn Tennis, Rackets, Squash Rackets, Badminton, Table Tennis, Eton Fives, and Rugby Fives.

#### Tennis.

Tennis, which is sometimes given a fuller title as either "Real," "Royal," or "Court" Tennis, has been called the King of Games, and it most

implies, it was originally intended to be played on grass, but, though the name "Lawn Tennis" has been retained, it is now played, not only on grass, but also on hard courts of various surfaces as well as indoors on wood.

The court and net are in accordance with the accompanying diagram, the outer long boundary lines being the limitations of the doubles court, and those close to and parallel to them being the boundaries for singles. Both server and receiver score, four points making a game, six games won making a set, and two out of three or three out of five sets making a match. The scoring is taken from Tennis, the points being scored "15," "30," "40," and "Game." The system of "vantage" games and sets is used. This means that if 40-all—called "deuce"—is reached, one player or the other must gain a clear lead of two points before winning the game. Whoever wins the first point after deuce is said to have the advantage. Similarly with sets: once 5-all has been reached, a clear lead of two games is needed to finish the set.

Service is almost invariably over-hand, and the receiver plays the service after one bounce. Thereafter, strokes may be "ground" strokes,

Diagram of Ground as marked out for Lawn Tennis.

certainly was the game of kings. It was popular with Henry VIII, and it is mentioned in Shakespeare's *Henry V*; but the first kings to play it were of France, for this is one of the rare instances of a very ancient game that was not invented in England.

Tennis is one of the most complicated of all games, and no description, however vivid, could give anyone who had never seen it played an accurate idea of what it is like. Most of the racquet-and-ball games use either a net over which the ball must be hit or walls against which it is hit, but Tennis uses both. Also, in most of the games in this group, players change ends after so many games, but, in Tennis, they may have to do so during a game. Matches are in games and sets, a player winning six games completing a set towards the two out of three or three out of five which will complete the match.

There are not a great many Tennis players in the country—there are fewer than a dozen courts—and no women play. People who do play, however, most of whom play other games as well, are almost unanimous in voting it the best of all games.

#### Lawn Tennis.

Lawn Tennis can claim none of the antiquity of the parent game, Tennis, but it is far more widely played, being extremely popular in almost every country in the world. Originally called Sphairistike—or "Sticky" by those who opposed its introduction—it really dates only from the seventies of the last century. It is a version of Tennis, designed primarily to be played out of doors and using a net but no walls. As its name

i.e., played after one bounce, or "volleys," i.e., played before any bounce. In doubles, either partner may play the ball, even if this means that one player takes several of his side's shots in succession. Each partner must, however, serve a game in turn.

In addition to being played by thousands of people in clubs and on public courts, Lawn Tennis is a "crowd-attracting" sport. The big annual tournaments, such as Wimbledon, Forest Hills, and Paris, are amongst the major sporting events of the year; as are the Davis Cup matches, open to teams of men from every country in the world, and those for the Wightman Cup, a women's contest between Britain and the United States.

#### Rackets.

Rackets is a very fast, strenuous court game, played exclusively by men, on a court measuring 62 feet by 31 feet. A game consists of 15 points, unless 13-all is reached, when the non-server can set the game to 3 or to 5: or unless 14-all is reached, when the non-server can set the game to 3. Once the game has been so set, the first player to win the prescribed number of points is the winner. Only the server scores, the non-server taking over service when he makes a winning shot. The ball when served must strike the front wall above a line called the "cut" line before striking any other part of the court, but, during the rallies, it may be played either on the volley or after one bounce. Rackets players do not always find it easy to keep out of each other's way, but they must do so as much as possible. If a player is impeded by his opponent, it is a "let," and the point is re-played.

## Squash Rackets.

Squash Rackets is a miniature version of Rackets, and was designed as such, being used originally as a useful form of preliminary preparation for the older game. It is played on the same lines as Rackets, but on a smaller court. Most games are singles, though doubles can be played, and, in the United States, there are a few special doubles courts, slightly larger than the normal Squash court.

Squash has far outgrown its original purpose, and is now a popular game in its own right, played by many people who have no intention of proceeding on to Rackets. It is played, in fact, by many women, though Rackets itself,

from that of Lawn Tennis. All the equipment is lighter, particularly the "shuttles" or "birds" which replace the ball. These are half-circles of cork in which feathers are fixed. They do not, of course, bounce, so all shots are volleys. Also, unlike Lawn Tennis, shots are made with the wrist, and not with the whole arm.

Because of these differences, it is frequently said that it is impossible to play both Lawn Tennis and Badminton well, as much play at one will spoil one's technique for the other. This, however, is not quite true. Most racket-game players are adaptable, and the eye for the moving object is the main requisite of both games, even though that object is moving very fast in one game and quite slowly in the other.

## DOUBLES COURT.

NOTE.—If it is practicable place the posts on the side boundary lines; failing this, place them at any distance not more than 2 ft. outside these lines.

A to B 2 ft. 6 in. A to C 15 ft. 6 in.  
A to D 22 ft.

## SINGLES COURT.

NOTES.—Place the posts on the boundary lines or not more than 2 ft. outside these lines.

The back boundary lines become the long-service lines.

A to B 15 ft. 6 in. B to C 6 ft. 6 in.

Diagram of Ground as marked out for Badminton.

like Tennis, is purely a man's game. Squash now has its own governing body, the Squash Rackets Association, and there are many championships, competitions, and matches every year.

## Badminton.

There are several stories of the origin of Badminton, the most popular being that it was invented by two guests at the Duke of Beaufort's house at Badminton in Gloucestershire, who spent a wet afternoon playing with the children's battledores and shuttlecocks. There seems to be no doubt that the game as we know it to-day did take shape at the estate of Badminton from which it took its name, but it is also likely that its basis was a game originally played in the Orient.

Badminton, which is both extremely popular already and growing still more popular every season, is, in some ways, a kind of indoor version of Lawn Tennis. It is played over a net, and it can take the form of either singles or doubles. In many respects, however, it is quite different from Lawn Tennis and more like some other court games. For one thing, only the serving side actually scores, the receiving side getting its reward for winning shots in that these end opponents' serving runs. Scoring does not follow the Tennis system, but goes up in single points.

The actual technique of playing is very different

At any rate, many players have reached an excellent standard at both games, and regularly play one during the summer and the other during the winter.

## Table Tennis.

Table Tennis was originally introduced—under the name of "Ping-Pong"—simply as an amusing parlour game. From there, it has now grown into a serious competitive sport with a properly constituted governing body; with many international, national, and lesser championships and tournaments; and with the ability to attract crowds of 10,000 spectators.

Resembling a miniature game of Lawn Tennis, the net is set on a table 9 ft. long by 5 ft. wide. The rackets are called bats and are like miniature Tennis rackets in shape, but have a striking surface of rubber. The ball is a small, very light celluloid one. Players serve series of five balls in turn, and a game is 21 points, both server and receiver scoring. Matches are usually the best two out of three or three out of five games. The service has to bounce first on the server's side of the net, and then on the other side, and thereafter all strokes are "ground" strokes, volleying not being permitted. "Vantage" games are played, as, if the score reaches 20-all, each player serves in turn, and the game continues until one has a clear lead of two points.

To prevent purely defensive play in championships, the officials have power to order the players to serve alternately, and to award each point not won by the server within 12 shots to the receiver. Doubles can be played, as well as singles.

Table Tennis is a very fast game, requiring perfect fitness and split-second reactions. It is interesting to note that many Lawn Tennis players have also played Table Tennis, and that several of these have found it desirable to retire from the fast table game long before they retired from the outdoor game.

### Eton Fives and Rugby Fives.

There are two different games of Fives, Eton Fives and Rugby Fives; and neither is strictly a racquet game, as the striking implement in each case is simply the gloved hand. Both, however, are court games, quite definitely belonging in the same category as Rackets and Squash. The two games are similar, involving the use of walls; but an Eton Fives court has the addition of a buttress or "pepper" jutting out from one side wall. Eton Fives is a doubles game, but singles as well are played in Rugby Fives.

### ROWING.

Rowing, meaning simply taking a boat out on the sea or on a river for a short period, can be a pleasant recreation and a healthy exercise: but competitive rowing is one of the most strenuous of all physical activities, requiring a long preliminary training programme to build up strength and stamina.

There are two main types of race rowing, and these should be made clear at the outset. In one, the rower actually does row, which means that he uses only one oar: in the other, he does not row, but sculls, i.e., he uses two oars. Rowing races are arranged to cater for crews of various sizes. The best-known type is eights, the crew consisting of eight men rowing, i.e., with one oar each, and a cox, who steers the boat. Then there are two types of race for fours, one with and one without cox. Here again the crew members have one oar each. There are three kinds of race for crews of two, pairs with cox, pairs without cox, and double sculls. The first two are for two men using one oar each, and the last is for two men with two oars each. Finally, there is single sculls, for one man using, of course, two oars. Crews of fours and pairs without cox and all scullers have, of course, to steer themselves.

Rowing is included in the Olympic Games; and, in Britain, there is a long series of river regattas each season, the most important being Henley, a four-day meeting which attracts entries from all over the world. There are also rowing regattas held on the sea. For these, crews are usually fours with cox, and they use heavier boats than the normal racing "shell." Oarsmen and scullers are graded either as Novices, Juniors, Junior-Seniors, or Seniors, passing from one grade to another as they win a race in each class.

Rowing provides Britain with one of its great traditional free spectacles, this being the annual race for eights between Oxford and Cambridge Universities, which is held in March or April every year on the Thames over a course of just over four miles between Putney and Mortlake.

Oxford and Cambridge are also responsible for one other type of race rowing. This is "Bump" racing; and it came into being because the rivers Isis (Oxford) and Cam (Cambridge) are not wide enough to take several crews racing abreast. The annual inter-College races are, therefore, bump races, the crews starting at intervals, and each trying to catch and bump the crew ahead—except, of course, for the first crew, which can concentrate on keeping ahead. When a bump is made, the two crews concerned pull in to the bank, and change places for the next day's programme. It is the ambition of each crew, of course, to make one bump on each day of the races.

### Canoeing and Punting.

Rowing is not the only form of racing in boats. Both canoeing and punting are organised sports, each with its annual programme of races.

Canoeing, which is an Olympic sport, is divided

into two types, Canadian canoes and kayaks, the latter being very much lighter than the Canadian. All canoe racing in Britain is in kayaks, and the headquarters of the sport is at Teddington, in Middlesex, the governing body being the Royal Canoe Club.

Punting has a unique distinction in that it is confined, not only to one country, Britain, but also to one river, the Thames. It has been rumoured from time to time that a similar sport is, or was, practised in Japan, but the British punting authorities are not satisfied that this has ever been proved to be true. Punting consists of propelling a long, narrow, flat-bottomed boat with a pole, the punter, of course, standing up. Punting headquarters is at Staines, also in Middlesex; and the ruling body is the Thames Punting Club, which organises annual championships for men and women amateurs and for professionals.

### SKATING.

Although the British climate is not one which makes ice-skating a normal, almost inevitable activity in this country, British people have always appeared to possess a natural talent for it, and to have practised it whenever opportunity offered. The history of British skating, particularly, perhaps, in the Fen district, but also in many other areas, goes back far beyond the days when records of these activities were first kept; and, half a century and more ago, dozens of people were making annual visits to Switzerland, where skating played a large part in their Winter Sports programme. In more recent times, the necessity either of going to Switzerland or of waiting for a "freeze-up" has been avoided by the erection of the indoor rinks. There are now about thirty of these, and enthusiastic skaters flock to them evening after evening, not only during the winter, but all the year round.

Not all skaters, however, skate on ice: for, if there are thirty ice rinks in Britain, there are over a hundred halls which are wholly or partly roller-skating rinks. Roller-skating is now such a popular recreation in its own right that it is not easy to remember that it was originally introduced long before the arrival of the indoor ice rinks, purely so that ice-skaters could continue to practise their figures when no natural ice was available. Its subsequent development was by fits and starts. There were terrific "crazes" when almost everybody roller-skated for a time, and there were periods when it seemed that no one did so. Then, roller-skating settled down. It became a regularly practised and popular recreation that went steadily on, often showing an increase in popularity, but no longer the subject of sudden crazes. To-day, both ice- and roller-skating have their huge bands of devotees, but there are also a great many people who practise and enjoy both. Ice-skating is an outdoor activity that has been brought indoors, while roller-skating is primarily an indoor recreation, which can also, however, be practised outdoors on roads, in parks, and on specially laid outdoor rinks.

Many people skate just for recreation, health and amusement, but there are others who, once they start, want to master the art as completely as possible, and welcome opportunities of testing their skill against that of others. There is, therefore, a very full programme of annual competitive skating events, properly organised, exactly as is the case with other competitive sports.

Competitive skating is not so much one sport as eight sports, each practised, in many cases, by people who have little knowledge of or interest in the others. These sports are figure, dance and speed skating and hockey, each of which can be done on either ice- or roller-skates. All these sports in Britain, with the exception of the two games of hockey, are governed by the National Skating Association, which was formed in 1879, originally simply to control the oldest of all skating sports, ice speed skating. It subsequently took control of the other branches of ice-skating, and of roller-skating, and it now governs all these through five special committees, these being the Ice Speed Committee, which is subdivided into a Fen Centre and a General Centre; the Ice Figure Committee; the Ice Dance Committee; the Roller Speed Committee; and the Roller Figure and Dance Committee. All these sports are the subject of

international, as well as national, competitions, and the N.S.A. enters selected British teams for international events, and is in membership with the international governing bodies, the International Skating Union (Ice) and the Federation Internationale de Patinage a Roulettes (rollers). There are World and European ice figure and speed championships, the latter consisting of outdoor races; and World and European roller figure, dance and speed championships, the speed events having separate outdoor and indoor meetings. Ice figure and speed skating are included in the winter section of the Olympic Games, but, despite efforts which have been, and are being, made, roller-skating has not yet achieved Olympic status. The World ice figure championships and the European roller figure and dance championships, as well as the World amateur ice-hockey championships, were all held in London during March and April 1950.

At home, the N.S.A. holds annual championships for amateurs and professionals in all branches of ice- and roller-skating. There are regular indoor speed championships, and outdoor ice speed events are arranged whenever possible. There are no outdoor roller speed events at the moment, though there were formerly. Efforts are now being made to find a suitable surface on which these events could be revived. In addition to these championships and to other competitions, the N.S.A. organises a series of Tests, with medal awards for any skater who reaches the particular standard. These tests give the enthusiast a chance to mark his, or her, progress from novice to expert in figures, dancing or speed skating on ice and rollers. In all, there are nearly fifty of these Tests, each branch being divided into 1st, 2nd, and 3rd class, with some additional intermediate stages, and special Tests for instructors.

Ice-hockey is governed by the British Ice-Hockey Association in England, and by the Scottish Ice-Hockey Association in that country. This sport, which is of Canadian origin, played six-a-side with substitutes permitted, and with a rubber disc called a puck instead of a ball, first began to win popularity in Britain soon after the First World War; and it reached the status of a major sport about 1936. There is a National League, but this is almost entirely dependent on players specially imported from Canada. These men are neither amateurs nor professionals, as ice-hockey recognises a third category, called independents, who receive generous expenses, but who are neither classed as fully fledged professionals nor eligible for amateur international teams or Olympic teams—for ice-hockey is included in the winter section of the Olympic Games. Below the National League is the Intermediate League, which consists of teams using British amateur players. There are also a number of teams composed of boy players, many of whom train under one or other of the various rink schemes to develop British players up to the Canadian standard. Incidentally, it is the view of some Canadian experts that this attempt to raise the British standard to that of Canada is not as hopeless as might appear. They point out that Canadian boys learn outdoors, and have ice for only about four months a year. In this country, the boys can train in the indoor rinks all the year round, so, though they may start later than the Canadians, they should progress three times as fast.

Roller hockey, or, as it is more usually called, rink hockey, is controlled by the National Rink Hockey Association. This game bears a much closer resemblance to ordinary outdoor hockey than does ice-hockey. It is played with a ball, and teams are five-a-side with one substitute permitted. It is purely an amateur game, so popular now that there are summer, as well as winter, league and cup competitions operating. There are World and European championships, the two titles being decided at one tournament. Britain is one of the leading rink hockey countries of the world.

Other games have been played on skates from time to time, but the only other skating game played regularly is Bandy. This is an outdoor ice game, closely resembling field hockey. Bandy originated in England, but it is no longer played here, though it is extremely popular in Sweden and the U.S.S.R. Badminton has been, and is, played on ice skates, but only as a stage show, and not as

a competitive sport. Some countries have tried Basketball on roller-skates, and it is possible that this game might develop and spread.

It is not particularly hard to learn to skate, but it cannot be done from books. The only way is to try it; and it is not necessary to engage an instructor until one can at least "go round." It is possible to practise to some extent, i.e., to get used to standing on skates, at home. Strong ankles, a good sense of balance, and plenty of confidence are needed. Skating is almost certainly more easily mastered if the beginner is a youngster, but plenty of adults have taken it up successfully.

## SWIMMING.

Swimming as a competitive sport, though it is extremely popular, is not, perhaps, generally given the attention usually paid to a major sport: but swimming as a recreation, indulged in purely for fun and without thought of serious competition, is one of the most popular pastimes in Britain. Actually, this accomplishment goes far beyond being merely a sport or recreation. It is a method of progression of which everybody should have at least some knowledge, for ability to swim might at any time enable one to save life. Incidentally, swimming shares with walking the distinction of being a perfect exercise. It exercises the whole body without straining it, and it can be practised as leisurely or as energetically as the swimmer wishes.

There are a number of different strokes used for propelling the body through the water. The one generally taught first, and the one required for all life-saving tests, is the breast-stroke. Other strokes, aiming at more speed, have been introduced from time to time, and these include the side-stroke, the over-arm, the trudgeon, and the crawl. Generally speaking, each of these has almost completely superseded its predecessor, and the crawl is now almost universal. There are two methods of swimming on the back, one, also very useful in life-saving, being something of a back equivalent to the breast-stroke, while the other, used in racing, is a back crawl.

As a sport, swimming has a regular place in the Olympic Games, and there are many other championships and competitions. The standard distances for races range from 100 yards to a mile; and there are also a number of longer annual swimming races, both in the sea and in rivers, ranging from a mile to five miles. In addition, there are in various parts of the world certain stretches of water which seem to act as a permanent challenge to strong swimmers. The most famous of these is, of course, the English Channel; and, although this has been conquered on a number of occasions, the swimming of it remains, and will always remain, a very considerable achievement.

The governing body of swimming is the Amateur Swimming Association; but another very important body is the Royal Life-Saving Society. This organises regular tests ranging from preliminary to very advanced, and concentrates on teaching the best methods of saving life in the water and of resuscitating the apparently drowned. All good swimmers should take the trouble to acquire at least some proficiency in this branch, for even a most powerful swimmer will experience considerable difficulty in attempting to save someone unless he or she has some idea of the best method of setting about it.

## Diving.

Akin to swimming in that it is a water sport, but in actual fact quite a different sport, generally attracting quite different people, is diving—also an Olympic sport. Diving in competitions entails the ability to use boards of various heights, and it is usually necessary to perform certain set dives and a number of voluntary dives, the latter being chosen from an approved list. In addition to the obvious requirement of nerve, the diver needs almost the same physical qualities as the gymnast: the ability to control the body in the air. Good swimmers are generally fairly big physically, but the best divers are usually much smaller and more compactly built.

## Water Polo.

It is not surprising that an actual team game, suitable for playing in the water, should have been

invented. What is surprising is that, up to the present, no one should have been able to work out a set of rules which would be accepted throughout the world: for, in its seventy-odd years' history, water polo has probably been the subject of more codes of rules than almost any other game.

The main object of the game is the scoring of goals. The ball used resembles a soccer ball, and the goals are similar in appearance to soccer goals, but all passes, shots, etc., are, of course, thrown. The chief difficulty confronting those who have tried to work out suitable rules has been the scope for, and the difficulty of detecting, fouls under the water. Players in almost every country that has taken up the game have, it seems, taken full advantage of these opportunities; and, though the game is included in the Olympic Games, it is always likely to cause an international "flare-up."

Fairly recently, however, a new set of rules, known as the South American rules, has been prepared; and it is hoped that these may be adopted internationally. Based on the rules of basketball, these rules ban all bodily contact between opposing players, and aim at a game in which skill, rather than brute force, should be the deciding factor. It also seems that these rules would make things much simpler for officials controlling games.

### WEIGHT-LIFTING.

Weight-lifting is a highly organised competitive sport included in the Olympic Games, and also in the Empire Games. It is tremendously popular on the Continent and in countries like Egypt, but it also has a very large following in Britain, where it is governed by the British Amateur Weight-Lifting Association. There are World, European, and British Championships; and, in this country, there are many inter-club and league contests throughout the season. For competitive purposes, weight-lifting competitions are divided into classes by body-weight, and there is a system, based on what is known as the Austin Formula, by which allowances can be made to compensate the lighter team in inter-club matches. In the event of a tie in actual poundages lifted in major Championships, the lighter man is the winner.

Altogether, there are forty-two recognised lifts, and the B.A.W.L.A. runs a scheme in which lifters somewhat below Championship class can win first-, second-, or third-class Certificates of Merit in any lift, no matter what their body-weight. Championship events are decided on three lifts, each competitor having three attempts at each.

Apart from those who lift weights as a sport, and who enter for Championships, there are many who use weight-lifting as a means of training for health and fitness and to improve their physique. It is without doubt the best means of bringing a physique which is below par up to, and above, standard. When using weight-lifting for physical training, the system is to perform certain lifts, doing a fixed number of repetitions of each with a weight of two-thirds or three-quarters of the known maximum poundage. Anyone taking up this form of training for the first time would be well advised to seek the advice of an experienced trainer or coach as to the schedule of lifts most suitable for the particular case. These coaches are not hard to find, for there are some 750 clubs scattered all over the country, all with experienced men willing to help new-comers.

Many leading exponents of other sports, especially of athletics, regard weight-lifting as an essential part of their training. Contrary to a widespread belief, it does not make one slow. Weight-lifters in competition, in fact, make some of the fastest movements known in sport.

Opinion as to the value of weight-lifting for women varies. There are no competitions for women, but quite a number use this method of training for health and to improve the physique.

### Strand-Pulling.

Closely akin to weight-lifting in that it is primarily, perhaps, a method of keeping fit which has been turned into a competitive sport is strand-pulling, which is the official name for exercises with a steel or rubber expander. A large number of different "pulls" are possible, and the strength and number of the strands on the expander can, of

course, be varied at will. There are now many championships and contests at this sport, the competitive side of which is controlled by the British Amateur Strand-Pulling Association.

### WRESTLING.

Briefly, the sport of wrestling is an individual combat in which the competitor, using only his bare hands, endeavours to throw his opponent down on his back so that both his shoulders are touching the ground. Wrestlers, like boxers, are divided into classes by weight, but generally speaking, the maximum poundages in each class are higher than those in boxing. There are several distinct styles of wrestling, each with its own set of rules; and the sport is practised by both professionals and amateurs.

Probably the most popular style in Britain is Catch-As-Catch-Can. In this, the wrestlers have considerable freedom of movement. They start apart, and they may try to throw their opponent either by grasping with the hands or by various forms of trip. As two evenly matched men might continue for a considerable time without either gaining a fall, most amateur contests are so regulated that a points decision can be given. The bout is limited as to time, the judges giving their decision if no fall has been obtained in that time. Obviously, in this type of wrestling, the bout may proceed with the men either on their feet or down on the mat; and something approaching a stalemate is possible. If, therefore, no fall has occurred after a certain number of minutes, the judges may require the contestants to stop and restart, either standing or on the mat, with one or other in the top position. Certain holds which might lead to serious injury are barred.

Also extremely popular is Cumberland and Westmorland wrestling, which is widely practised in those counties and in Scotland. In this, the wrestlers do not start apart, but each clasps his hands together behind the other's back, and all throws are done by the legs. The breaking of an opponent's hold constitutes a fall. The initial hold, is, therefore, of tremendous importance, and the actual taking of it often takes far longer than the actual bout.

A third form of wrestling found in Britain, though only in a certain part of it, is Cornish wrestling. Here, the contestants wear rough canvas jackets, and all holds must be taken by these.

Græco-Roman wrestling has always been the most popular style on the Continent, but it has never been very popular with British wrestlers. The competitors start apart, as in Catch-As-Catch-Can, but no hold may be taken below the waist. A bout continues until a fall has been won, and this sometimes takes a matter of hours, rather than minutes. As may be imagined, this version of the sport can be rather slow to watch, and, at one time, handicap matches were popular. These consisted of bouts in which one wrestler, supposed to be much better than his opponent, undertook to win a fall, or a certain number of falls, in so many minutes. If he failed to do this, or was himself thrown, then he was the loser. About half a century ago, wrestling was a popular music-hall entertainment in London, wrestlers like Hackenschmidt—known as the "Russian Lion," though he was actually an Estonian—winning tremendous popularity. Græco-Roman was the style generally used in those days.

Most professional wrestling in Britain and America to-day is in what is known as the "Free" or "All-In" style. Few holds are barred, and those that are are frequently employed. The contestants also seem to feel free to punch or kick each other. The same men wrestle night after night in different halls, and the sporting public are disinclined to take it very seriously. Some people go for amusement, as they would go to a music hall, and most of them regard it as a stunt, rather than as sport. In America, promoters have attempted to keep public interest alive by staging bouts in a ring which has been turned into a sea of mud, or which has been filled with fish. Such devices might succeed in attracting the public once or twice, but they also give considerable support to the theory that the whole style is a stunt likely to do a lot of harm to a first-rate sport—as, indeed, it has already done.

Wrestling, like athletics and swimming, is a perfectly natural sport, and it is of great antiquity. It is very popular in Oriental countries, and India, China, and Japan all have their own styles. Japan, in fact, has at least two, one of which is worth some attention.

This is Judo, more often, though less correctly, called Ju-Jitsu. This is practised in England, but, although it is a sport, it is more often taken up as an effective method of defence against a physically stronger or better-armed attacker. Requiring deep study and a thorough knowledge of anatomy, but not calling for a particularly strong physique, it consists partly of defence by knowing how to

sustain nasty falls without injury, and attack by locks which give the opponent a choice between capitulation and a broken bone, and by paralysing nerve centres. So potentially dangerous are the various locks that, when practising, people are warned to release any hold the moment their partner requests this.

Wrestling, particularly in the Catch-As-Catch-Can or Cumberland and Westmorland styles, is a wonderful exercise, whether one desires to go in for competitions or not. The value of it can be gauged from the fact that it can be continued to, or even taken up at, quite an advanced age.

## INDOOR GAMES AND PASTIMES

### BRIDGE.

#### Auction.

Auction Bridge is a game for four, two partnerships of two opposing each other. The partners sit facing each other. Selection of partners is generally decided by cutting cards, the two players drawing the higher cards opposing the other two. Partnerships can also be decided by mutual agreement. The player to draw the highest card is the dealer. The complete pack is dealt, each player receiving thirteen cards.

The cards having been dealt the dealer starts the bidding and it continues in rotation.

The value of the suits is as follows:—

Clubs	6 points per trick
Diamonds	7 points per trick
Hearts	8 points per trick
Spades	9 points per trick
No-trumps	10 points per trick

It will be seen that a contract of three Clubs (18 points) will not overcall a contract of two No-trumps (20 points). When two contracts have the same points value, as, for example, two Spades and three Clubs, the extra trick prevails.

If a contract is doubled the trick score is doubled, and if redoubled the trick score is redoubled.

Any player may pass, but should he make a bid it must be sufficient to overcall the previous bid. A player making an underbid can be penalised—the player on the offender's left having the option of closing the bidding at the previous bid or demanding that the offender make a proper bid, in which case his partner is debarred from further bidding unless the opposing side double or make another bid.

Should a player bid out of turn the player on his left may demand a new deal.

All tricks in excess of six made by the contracting side score towards game, to make which 30 points are required. For example, should the final contract be two Diamonds and nine tricks be made, the score to declarer's side is 21 points below the line. This 21 carries forward and can contribute towards game. If at any time a partnership score a game, any outstanding score below the line automatically ceases to rank towards game.

The first side to score two games wins the rubber and receives a bonus of 250 points above the line.

All scores for honours, penalties, and bonuses are scored above the line and are included in the final score—they cannot, however, contribute towards making a game.

The following bonuses are awarded for honours:—

Holding 3 honours . . . . .	twice the suit value
i.e.,	3 honours in Hearts receive a bonus of 16 points
Holding 4 honours . . . . .	4 times the suit value
Holding 5 honours . . . . .	5 times the suit value
Holding 4 honours in one hand . . . . .	8 times the suit value
Holding 4 honours in one hand and one in partner's . . . . .	9 times the suit value
Holding 5 honours in one hand . . . . .	10 times the suit value.

At No-trumps, the honours count for three Aces is 30 points, for four Aces 40 points and for four Aces in one hand 100 points.

Penalties are awarded for defeating a contract.

For each trick by which the contract fails the penalty is 50 points. If the contract is doubled the penalty is 100 points per undertrick, and if redoubled 200 points per undertrick.

Bonuses are awarded for making a doubled or redoubled contract. For making a doubled contract the declarer receives a bonus of 50 points and a further bonus of 50 points for each trick he makes over and above the nominated contract. If redoubled, the bonus for making the contract is 100 points with a further bonus of 100 points for each overtrick. These bonuses are in addition to the doubled (or redoubled) trick score recorded below the line.

A bonus of 50 points (also recorded above the line) is awarded for making a little slam—twelve tricks—in either a suit or No-trumps. For a grand slam—thirteen tricks—the bonus is 100 points. These bonuses are not affected by doubling or redoubling.

The player who first named the suit for his side in which the contract is to be played becomes the declarer, and the opponent on his left makes the initial lead. When this has been done, declarer's partner (known as dummy) displays his hand on the table.

Dummy may not draw attention to any irregularity or to a revoke, nor may he claim any penalty. If his partner fails to follow suit, he can ask him if he has no cards in the suit led. He can draw attention if too few or too many cards have been played to a trick, or if the trick has been gathered by the wrong side. He may discuss questions of fact and correct any claim made by the opponents to which they are not entitled. He may not warn declarer not to lead from the wrong hand.

The player on the left of the declarer makes the opening lead, and dummy's hand is exposed. Each player must follow suit if he is able to do so. The highest card of the suit wins the trick unless it is trumped. The winner of the trick leads to the next trick.

If a player did not follow suit when he could have done so, he has revoked. The revoke becomes established if the offender or his partner has led or played to the next trick. If the revoke has not been established, the offender may correct it. When established, the penalty for a revoke is two tricks. Subsequent revokes incur a penalty of one trick each.

Such penalty tricks can, however, be claimed only from tricks taken subsequently to the revoke. If no subsequent tricks are taken by the offending side, there is no penalty. "Subsequent" includes the actual trick in which the revoke occurred. A revoke in the twelfth trick cannot be established.

Tricks taken as a result of the application of this penalty count and score as though made in actual play.

If declarer leads out of the wrong hand he may not withdraw the card unless an opponent requests him to do so. Should this happen, the card incorrectly led is restored to the hand and there is no further penalty. If an opponent leads from the wrong hand, declarer may demand that a certain suit be led by the right hand, in which case the exposed card is restored to its owner without further penalty. Alternatively, he may elect to treat the card as a penalty card and allow the right opponent to make any lead he likes. The declarer can "call" the penalty card at any time, and its owner must play it provided that by so doing he does not revoke. Declarer, however,

cannot prevent the holder of the exposed card from playing it at any time should he have a suitable opportunity.

Dummy may not suggest the play of a card by touching it or in any other way. If he does so, either of the opponents can insist that the card shall or shall not be played.

Any player except dummy can claim a revoke penalty, or call his partner's attention to an offence, but only the player entitled to claim can exact a penalty.

### Contract.

At Contract Bridge, only the tricks contracted for are scored below the line, the score for additional tricks being recorded above the line. A declarer contracting to make, say, Two Spades, needs eight tricks to fulfil his contract, while a contract of Four Hearts needs ten tricks. In every case the number of tricks contracted for is over and above six.

The score for tricks in a major suit (i.e., Spades or Hearts) is 30 points; for a minor suit (i.e., Diamonds or Clubs) 20 points; whilst in No-Trumps, the first trick counts 40 points and subsequent tricks 30 points. A game consists of 100 points, so that it is necessary to bid and make Four Hearts or Four Spades, Five Diamonds or Five Clubs, or Three No-Trumps, to produce a game. Should a declarer play a hand in, say, Four Diamonds and make eleven tricks he scores 80 points below the line and 20 points above it. The 80 points below the line carry forward, so that a contract of One in any suit or One No-Trumps would be sufficient to make game next time.

The additional score above the line is included in the final total, but does not contribute towards the making of a game. It is thus desirable that the contract should, whenever possible, be for a sufficient number of tricks to make game. It is galling to play a hand in a contract of One Spade and make eleven tricks, since only 30 points out of the 150 scored are recorded below the line and rank towards a game.

On the other hand it is foolish to overbid the hand in order to reach a game bid that cannot be fulfilled.

The suits rank in the following order: the lowest being given first, Clubs, Diamonds, Hearts, Spades, No-Trumps being the highest. Majority bidding applies, that is to say a bid of a greater number of tricks overcalls the bid of a lesser number, irrespective of suit value. Thus a bid of Five Clubs, although yielding only 100 points, overcalls a bid of Four Spades, which would yield 120 points.

A rubber is completed when one side scores two games. If the opponents have not scored a game (i.e., it is a Two-game rubber) a bonus of 700 points is awarded; if it is a Three-game rubber the bonus is 500 points. When either side has scored a game it becomes vulnerable, the effect of which will be discussed later.

When adding up the score the total points are counted, whether above or below the line. The difference between the totals scored by one side and the other is the margin by which the rubber is won. If the stakes are estimated to the nearest hundred, a difference of 50 is ignored. Thus a difference of 450 counts as 400 for stake computation. In the case of an unfinished rubber, a bonus of 300 points is awarded for a game and 50 points for a part score. If both sides have a part score (even though they differ in size) there is no bonus.

The desirability of arriving at the optimum contract, i.e., to undertake to make as many tricks as the partnership hands are worth, and no more, has led to the introduction of a number of bidding systems, among which the most popular are the Approach-Forcing system introduced by Mr. Ely Culbertson, the Acol system, the Two Club system, the Vienna system, and the CAB system. The object of these systems, as to the respective merits of which there is considerable rivalry, is to provide for the interchange between partners of as much information as possible within the limits of a few bids.

Penalties are incurred for failing to make the contract finally reached. If the declarer is not vulnerable the penalty is 50 points per under-trick, if vulnerable 100 points per under-trick.

If the contract is doubled by an opponent the penalties are as under:—

	Not Vulnerable.
100 for the first under-trick.	
200 for each subsequent under-trick.	
	Vulnerable.
200 for the first under-trick.	
300 for each subsequent under-trick.	

If the declarer redoubles the penalties are twice as severe.

If a doubled contract is successful, the declarer scores twice as much for the tricks he has undertaken to make. Thus a contract of Two Spades doubled and made gives a score below the line of 120 points, giving declarer a game where he had contracted only for a part score.

\* Overtricks score 100 each above the line if declarer is not vulnerable, and 200 each if vulnerable. All of these scores are doubled if the contract is redoubled. In addition, the declarer scores a bonus of 50 points above the line for any successful doubled or redoubled contract.

Bonuses are awarded for making slams, provided that they are bid. If the side making the slam are not vulnerable, the bonus is 500 for a small slam (12 tricks) and 1000 for a grand slam (13 tricks). If vulnerable the bonuses are 750 for a small slam and 1500 for a grand slam. Doubling or redoubling does not affect the slam premiums.

If a player (whether declarer or opponent) holds Four honours in one hand in the suit of the final contract he receives a bonus of 100 points. For holding Five honours in one hand the bonus is 150 points. Four Aces in one hand score 150 points providing that the final contract is in No-Trumps.

Various methods have been devised for computing the value of a hand, the Milton Work count being probably the most popular. In this the player reckons Four for an Ace, Three for a King, Two for a Queen, and One for a Knave.

To open the bidding a player should have 12-13 points, although this figure can be reduced if the hand has compensating distributional strength.

An opening bid of One No-Trumps denotes a balanced hand and a holding of 16-18 points.

An opening bid of 2C, 2D, 2H or 2S indicates a very strong hand, and a partner must respond even though his hand is completely worthless. The conventional response to indicate a worthless hand is Two No-Trumps. An opening bid of Two of a suit must be kept open until a game bid is reached.

An opening bid of Two No-Trumps shows a balanced hand and a count of 20-22 points.

Responses to an opening bid depend on the shape and strength of the responding hand. Over an opening bid of a suit, responder can bid another suit at the range of one on a point count of 7 or more. If it is necessary to bid at the range of two he should hold 9 or more. A responder unable to do either of these things, but having 5-8 points should respond One No-Trumps. This response of One No-Trumps, sometimes called a "courtesy" response, is made to enable the opener, should his hand warrant it, to make a further constructive or forcing bid. For example, the opener's hand might fall just short of the "opening Two" standard, but the knowledge that his partner holds 5-8 points might now enable him to bid game.

A forcing response is made by jumping the bidding in another suit. For example

N.	E.	S.	W.
1D	—	2H	—

Here South, by making a bid at a higher level than necessary, is saying to his partner "There is at least a game here and possibly a slam."

The opener must, of course, respect this force and keep the bidding alive until game is reached.

A double raise in the opener's suit, i.e.,

N.	E.	S.	W.
1D	—	3D	—

has similar implications and shows a good fit in the suit bid.

A bid of Two No-Trumps over an opening bid shows a balanced hand and a count of 9-11. Opener should pass if he opened on a minimum hand and should bid Three No-Trumps if he holds any additional values.

After a one-over-one response a bid of Two No-Trumps by opener shows a holding of 16 points. In the sequence

N.	E.	S.	W.
1D	—	1H	—
2N.T.			

North is showing 16 points. South by his one-over-one response of One Heart has already shown 7 points. If he holds any additional values he should bid Three No-Trumps. Roughly speaking a combined count of 25 is required to produce Three No-Trumps, although 24 is generally sufficient if one of the partners holds a Five-card suit.

A second-round force can be made by a bidding sequence such as the following:—

N.	E.	S.	W.
1S	—	2D	—
3H	—	—	—

Here North was not strong enough to make an opening "forcing two" bid, but now that his partner has shown at least 9 points by his "two-over-one" response he does not want to stop short of game.

A player when making an opening bid guarantees that he will find a rebid over his partner's response, unless it be the "courtesy" response of One No-Trump, which he may pass.

In order that this rebid can be made without raising the bidding too high, use is sometimes made of a "prepared" club bid. This can be made on a three-card suit. Its principal merit is that it gives partner an opportunity of responding at the level of one, should he hold suitable values. Had the opening bid been One Spade or One Heart responder may have held insufficient strength to bid Two of a suit and be compelled to bid One No-Trump which may not be the best contract. The "prepared" club bid should not be used on a hand containing a rebiddable (i.e., Five-card) major suit.

For the successful bidding of slams, it is often essential to have knowledge of partner's Aces and Kings, because the contract frequently depends on first- and second-round controls.

As an aid to procuring this knowledge, various slam conventions have been introduced, the most popular being the Blackwood Convention, the Culbertson 4-5 No-Trump Convention, and the Norman Convention.

In the Blackwood convention a bid of Four No-Trumps after trump agreement has been reached asks partner to say how many Aces he holds. This he does as follows: Five Clubs shows no Aces, Five Diamonds one Ace, Five Hearts two Aces, Five Spades three Aces. A bid of Five No-Trumps now invites the same information about Kings. A response of Six Clubs shows no Kings, Six Diamonds one King, Six Hearts two Kings, and so on.

In the Norman convention the information is obtained in one response. A bid of Four No-Trumps is replied to as follows: Counting one point for Aces and a half for Kings: Counting one point for Aces shows less than 1½, Five Diamonds shows 1½, Five Hearts shows 2, Five Spades shows 2½, Five No-Trumps shows 3, Six Clubs shows 3½ and so on. It is true that a response of, say, Five Hearts shows a count of 2, which may consist of two Aces, one Ace and two Kings, or four Kings, but the player who initiates the slam try can generally place the cards by reference to his own holding.

In the Culbertson 4-5 No-Trump convention, the player who makes the Four No-Trump bid announces that he holds Two Aces and a King of a suit that has been bid, or alternatively Three Aces. Responder signs off in the lowest suit bid by the partnership. Holding one Ace he bids the suit containing it (if it happens to be in the lowest suit bid by the partnership he must make a jump bid). Holding two Aces, or one Ace and the Kings of all the suits bid by the partnership, he responds Five No-Trumps.

Another Ace-showing method is that known as Asking-Bids, which although extremely valuable is somewhat difficult and has not been adopted so widely as it merits.

Many mistakes can occur during the auction, and players are advised to consult the official Laws of Contract Bridge (the last edition was in 1948). These Laws are too comprehensive to be

included fully in this summary, but the following are brief references to some of the more frequent infringements.

If a player during the course of the auction makes an insufficient bid, he is required either to pass or to make a sufficient bid. If he makes the lowest sufficient bid in the same suit there is no penalty, but if he makes any other bid or if he elects to pass, his partner must pass for the remainder of the auction.

If a player makes a call out of rotation it is void, and the auction reverts to the player who was correctly entitled to call. If the call out of rotation was a pass, the offender must pass when it is his turn to call. If it was another bid, his partner must pass throughout the rest of the auction.

A player is entitled to ask for a bid (or a sequence of bids) to be repeated. He has no redress if he mishears or misunderstands a bid.

After the final contract is determined, that is when any bid, double or redouble has been passed by three successive players, the declarer is the partner in the contracting side who first nominated the suit (or No-Trumps) in which the hand is to be played. Thus if the bidding sequence is

S.	W.	N.	E.
1N.T.	—	3H	—
35	—	3N.T.	—

the declarer is South and not North, although North actually bid the final contract.

The opponent on the left of the declarer makes the opening lead and declarer's partner's hand is then placed on the table.

Declarer's partner, known as "dummy," has few rights, and he forfeits these if he looks at any of the cards in any of the other players' hands. If he has not looked at any cards other than his own he is entitled to give or obtain information as to the laws, to point out a revoke, to draw attention to an irregularity and to try to prevent one that is apparently about to be committed. He can, for instance, remind partner from which hand he should lead should declarer apparently propose to lead from the wrong hand.

If a declarer leads out of the wrong hand, either defender can demand that he leads from the correct hand. The card led is replaced, and the declarer, provided that he can do so, must lead a card in the same suit.

If a defender leads when it is the turn of the declarer (or dummy) to lead, the card becomes an exposed or penalty card, and the lead reverts to the correct hand.

If a defender leads when it was his partner's turn to lead, declarer may prohibit the lead of that suit (in which case the exposed card is restored to its owner without further penalty), or may allow the correct defender to lead any card he likes, in which case the card incorrectly led becomes a penalty card.

A penalty card must be played at the first legal opportunity, whether by following suit, by leading, discarding, or trumping. Should a defender have two or more penalty cards, declarer may stipulate which of them is to be played.

## CHESS.

Chess, the greatest of all board games and a game of pure skill, originated in the Orient, and has a known history of some 1500 years. Eastern players had reached a high level of skill, but the greatest advances in the game were made in Italy during the fifteenth and sixteenth centuries. From time to time in the early days, the value of the pieces and their moves were the subject of changes, but the game as we know it to-day dates from the sixteenth century.

The board contains sixty-four squares in eight rows of eight; and each player has sixteen pieces, one set being white and the other black or red—always referred to as black, whether this is actually so or not. A toss decides possession of white, which always starts. The object of the game is the capture of the opponent's King, no matter how many pieces are lost in doing so, nor how many other opposing pieces remain uncaptured. If the King could be captured on the next move, it is in check. It must then immediately move out of check, and, if unable to do so, it is check-mate, and

the game is over. If the King, though not in check, cannot move without moving into check, and the player has no other piece to move, then it is stale-mate, and the game is a draw. Incidentally, there is a school of thought which holds that stale-mate should be considered a win for the attacker. Games may also be drawn if neither player has sufficient pieces left with which to force a victory.

Apart from the King, each player has a Queen, two Bishops, two Rooks—often, quite wrongly, called Castles—two Knights, and eight Pawns; and these can move only in accordance with rigid laws. The following diagram shows the Pieces in the initial position of the game. Notice that the bottom right-hand corner square is a white one.

(The initial position as seen by White)

Each line of squares across the board is called a "rank"; each line of squares up and down the board is known as a "file." The permitted moves are as follows:—

The **KING** can move one square at a time in any direction, always provided that it does not move into check.

The **QUEEN** can move in accordance with the powers described below for both Bishops and Rooks.

The **BISHOPS** move diagonally, as many squares as desired from one to the extent of the board.

The **ROOKS** move straight along the ranks or files, again as far as is desired.

The **KNIGHTS** move, or jump, as shown in the following diagram. Stationed away from the

(The Knight's Move)

side of the board and on a black square, the Knight illustrated may move to any of the white

squares nearest to him but not immediately adjacent. The jump is made one square along a rank or file and one square in an oblique direction.

The **PAWNS** move straight forward, one square at a time, except that a Pawn may advance two squares on its initial move, though it need not do so. Pawns capture by moving one square forward and one either to left or right. Pawns reaching the eighth rank can be replaced by any other piece, a Queen usually being chosen.

Castling is a special move, which a player may make once and once only during a game. It is a double move, serving both to place the King in the comparative safety of the side of the board and to bring a Rook into play. The King is moved two squares towards the Rook, which is placed on the last square passed over by the King. This move cannot be made if the King is in check, nor if any of the squares passed over by the King are in check. The squares between the King and the Rook must be clear, and neither piece must have moved previously during the game.

As games of Chess can be recorded, the aspiring beginner of to-day may play over "Master's" games of past years, may enjoy current games no matter in what part of the world they are played, and can record its own games.

### Draughts.

Draughts—called Checkers in America—is another game played on a chess board. It is much simpler than Chess, but this does not mean that it is devoid of skill. It is extremely popular and extremely old—older, perhaps, than Chess.

Each player has twelve pieces or "men," all of them being alike. Only the thirty-two squares of one colour, say, black, are used; and the starting position of the pieces is on the twelve black squares of the first three rows of the board. The move is one square diagonally forward at a time, except that a man reaching the eighth row becomes a King—usually denoted by "crowning" with a piece previously captured—and it can then move one square diagonally forward or backward. The object of the game is the capture of all the opponent's pieces. A capture can be made when there is an opposing piece on a square to which normal move could be made, and a vacant square behind the opposing piece. The capturing piece then jumps over the opposing piece, which is removed from the board. If the arrangement of pieces and vacant squares permits, a capturing piece can hop over several opposing pieces in one move. Any piece in a position to effect a capture which does not do so is removed from the board, or "huffed."

### DARTS.

There has been no more phenomenal sporting development during the second quarter of the twentieth century than the growth in popularity of Darts. This game has, of course, been played in one form or another for much longer than twenty-five years, but it is only comparatively recently that it has reached the status of one of Britain's most popular pastimes. Originally, it was a casual amusement, confined almost entirely to public-houses and country inns. These are still the scene of hundreds of thrilling matches every year, but they are now far from being the game's only home. Clubs, canteens, factories, offices and private houses all have their boards; and there are numerous leagues and team and individual competitions operating, right up to a National Championship. The prizes and trophies rival those of any other sport for size and value, the matches are widely reported, and the attendance for the bigger contests is limited only by the size of the hall. Nor is all this attention misplaced, for Darts, far from being merely a casual amusement, is a real sport, testing steadiness and co-ordination of hand and eye, and calling for quick thinking. It is a test of sheer skill, and luck plays little part in it.

The board, which is circular and usually made of elm, has a diameter of 18 inches and is 2 inches thick. It is usually marked on both sides, so that a side which has been much used can be treated—by soaking it in water—and rested. It is divided into segments numbered from 1 to 20, but not consecutively, 1 being a long way from 2, and 19 from 20. All dart boards are marked

in the same way, and the first thing a beginner has to do is to get to know the order of the numbers on the board. In the centre, there are two small rings, the "bull" or "dossier" and the "outer". The bull counts 50 and the outer 25. The board is so placed on the wall that the bull is exactly 5 feet 8 inches from the ground. The darts, which are feathered and made of wood or metal, are thrown from a line, called the "hockey," 9 feet away from the board.

The actual marking of the board contains two further, most important complications—the "double" and "treble" rings. These, like the segments, are marked with wire, and they go right round the board. The double ring is at the extremity of the circular board, and consists of two wires, which, as they circle the board, mark off a portion of each segment  $\frac{1}{2}$  inch wide. The treble ring is exactly the same, but is set between the double and the bull, rather nearer the bull. Darts in these rings count double or treble the value of the segment.

Straight-forward matches may be singles between two players, doubles between two pairs, or team contests between sides of four or eight. A "throw" consists of three darts, and, in singles, each player in turn takes a complete throw. In doubles and team matches, each time it is the turn of a side, then the particular player of that side whose turn it is throws. It is not permissible for the best player on a side to throw for one of his team-mates.

Matches are for a certain number of points, always an odd number, usually 101, 201, 301, 501, 801, or 1001, the lower totals being used for individual, and the higher for team contests. Most matches are decided by the best two out of three games or "legs." The right to throw first is decided by each player or one player from each side throwing for the bull, the best throw taking precedence. First throw is valuable, for, in a short game of, say, 101, an expert might run out with his first three darts, without his opponent having a throw, this being possible by use of the doubles and trebles. The score, which is marked in chalk on a slate near the board, is always counted downwards, players being told how many they need, rather than how many they have scored.

Conditions for matches vary, but one of two particular methods is almost always used. These are, first, "straight start and finish on a double," and secondly, "start and finish on a double." In the first case, the first player steps up and immediately starts scoring whatever he throws, while, in the second case, no score counts until one double has been registered. To win, a player or team must get the exact number required. If too many points are scored, the whole of that particular throw counts nothing, and the total remains unaltered. The exact number needed can, of course, be scored with any dart, and it is not necessary to complete a throw by scoring it with the third dart. The rule about finishing in the double ring applies in virtually every competition.

No mention of darts would be complete without reference to at least some of the many popular variations on the straight-forward game.

One of these is "Round the Clock." In this, each player has to throw one dart in each segment in turn, starting with number 1 and ending either in double 20 or in the bull according to previous agreement. A player who advances his position during a throw has another throw, and so on until he throws three darts without scoring in the particular segment he has reached. A variation of this variation is "Shanghai." In this, the players aim each dart of the first throw at number 1, and count whatever they score in that segment, doubles and trebles having their full value. For the next round, the players, including any who have failed to score in number 1, move on to number 2; and so on until number 9, which is the last round. Any player failing to score at least something in number 5 is "shanghaied" and has to drop out.

Other variations take the form of darts versions of other games, "Cricket" being amongst the most popular. In this, the player who is "batting" scores whatever he makes over 40, while the player who is "bowling" throws only at the bull, and counts one "wicket" for every dart in the

outer and two for those in the bull. When the fifth wicket falls, the sides change over. The batting side always throws first in this game.

Shove-Ha'penny also has its darts version, the players having to get three darts in each segment from 1 to 9, and three in the centre. As in proper shove-ha'penny, players can claim for themselves any darts in excess of three placed in any segment by the opponent.

In "Fives," a player scores only if his total for three darts is exactly divisible by 5. If, for instance, he actually gets 40, he scores 8; but if he gets 39, he scores 0. These games are usually 50 up.

### SHOVE-HA'PENNY.

Shove-Ha'penny is one of the old English games, which is still played enthusiastically, especially, perhaps, in inns and public-houses. The equipment consists of a board and the halfpennies. The board is made of wood or slate; and it is divided by parallel lines drawn across it into nine equal spaces or "beds." On some boards, the divisions are marked by metal strips, which can be raised to check the result of a "shove." The edges of the board are cushioned. The halfpennies may be actual halfpennies, preferably those worn smooth by constant use; but they are more often—always in the more important competitions—round metal discs.

The object of the game is to shove the halfpennies into one of the nine beds, the shoving usually being done with the ball of the thumb, though any part of the hand may be used. The winner is usually the player who first succeeds in placing three halfpennies in each of the beds, the players shoving in turn, and each turn consisting of five halfpennies. To decide first turn, each player shoves one halfpenny for the number nine bed, the best effort taking precedence. The score is chalked up, the usual method being to mark straight strokes for the first two halfpennies in a bed, with a cross for the third.

Halfpennies that "cannon" off another halfpenny score, provided that neither has touched the cushion. Discs or halfpennies that touch the cushion do not count, and any knocked off the board cannot be used. Should a player actually place more than three halfpennies in any one bed, his opponent can claim the excess discs, if he needs them, except that the final point of a game cannot be won in this manner.

Touching a halfpenny before all have been shoved, removing one or more before the score has been counted, and playing out of turn, are all fouls. The penalty for the first two is the loss of any points scored in the turn, and for the last, the loss of the next turn.

### WHIST.

Whist could, perhaps, justifiably be called the standard card game. It has never excited quite the furore of Bridge but it is long established and very popular, both with family parties and at Whist Drives. It is probably the first card game, apart, perhaps, from a few simple games depending chiefly on luck, which most people learn, and a thorough knowledge of it is a sound foundation for the embryo card player.

It is played by four people, two partnerships of two opposing each other, and with a normal pack of cards. The partners sit at opposite corners of the table; and, the cards having been shuffled and cut for trumps, are dealt out singly until exhausted. The cards are then taken in hand and played out in 13 tricks of four each, the player on the left of the dealer having first lead; and the winner of each trick leading off in the next. Ace is highest card—except in cutting, when it is reckoned lowest—king, queen, and knave rank next in order, and then from ten downwards. The higher card of any suit takes the lower, unless the trick be trumped by a player unable to follow suit; and the tricks are gathered up by one of the pair winning them, as made.

It is necessary to concentrate, to watch the cards played, and to endeavour to "place" the unplayed cards. This comes with experience, as does a full understanding of such unwritten rules as "Second in hand plays low" and "Third in hand plays high"; and as does a knowledge of when to disregard the unwritten rules.

Three-handed Whist is also possible, one suit being discarded.

### Knock-out Whist.

Knock-Out Whist is a version of the game suitable for more than four players. However many players there are—there should not be more than six—each is dealt eight cards to start with. The dealer—this will have been decided by cutting—then examines his cards, himself selects trumps, and leads. The other players must follow suit if they can, and, if they cannot follow, they may trump. Each player plays as an individual and gathers as many tricks as he can. The player winning the most tricks in the round—ties are settled by cutting—deals for the next round, in which each player receives only seven cards. The dealer then chooses trumps and leads; and so on, the third round consisting of six cards each, and the next five. From the round of four cards downwards, any player failing to win at least one trick drops out. From this it follows that the game finishes as soon as one player wins every trick in a round from the four-card round onwards.

At first glance, it might seem that the dealer having both the right to choose the trumps after he has seen his cards and the lead must sweep the board, but this rarely happens. The full pack is not in use, so luck plays a bigger part than it does in ordinary Whist; and a part which increases as the game progresses and fewer cards are used.

### Solo Whist.

A game in which the four players act independently, unless there be "proposal" and "acceptance," when the two partners play together against the other two. Play is as at Whist. The cards are all dealt in four threes and, the final round singly, dealer facing his last card to

indicate trumps. The player on dealer's left may then "declare." If he, with a fairly strong hand, thinks he and a partner could make eight tricks, he calls "I propose," and may be accepted by any one of the other players in their turns, when the game proceeds, should there be no higher call. He may, however, call "Solo," which is a declaration that he intends to try to win five tricks against the combined efforts of the other three players. He may go higher and call "*Misère*," which means that he undertakes not to win any trick, and in this call there is no trump suit. He may declare still higher and call "*Abundance*," to make which he must win nine tricks, making any suit he chooses to nominate trumps, always providing that a call of Abundance in trumps—Royal Abundance—would take precedence over a call in another suit. It should be noted that a player going Abundance does not lead unless it is his normal turn to do so; and that the first round is played on the previously nominated trumps. Players going Abundance should, therefore, refrain from announcing their trumps until this first round is completed, unless, of course, it is necessary to state Royal Abundance in order to overcall. A very poor hand does not "declare" but "passes"; though the first player to call, having "passed," may accept a proposer, should the other players not do so or make a higher declaration, the declarations ranking from Abundance downwards, the lead going by rotation. *Open Misère* is a higher call than Abundance, its declarer exposing his hand after the first trick; and *Abundance Déclarée* is the highest call of all—in which he who adventures upon it must take every trick. He has, however, the right to nominate the trumps and to lead.

## OLD ENGLISH GAMES

The oldest English games are very old, for games existed before the Norman Conquest, two, Harpastum and Camp-ball, being distinct, if rough-and-ready, ancestors of football.

Cricket, too, had its forerunners, including Creag, Cat and Dog, and Rounders. Creag, which was known at the time of Edward II, used a curved stick called a "cric" as a bat, while a tree-stump served as wicket. Cat and Dog, which came later, was a game for three, two batsmen defending holes dug 13 yards apart, and trying to hit away the piece of wood that the third player aimed at the holes, the bats being the "dogs" and the piece of wood the "cat." It is interesting to note that American baseball's accepted ancestors are games called One Old Cat and Two Old Cat: a clear indication of a common origin for cricket and baseball. Rounders, of course, is well known and still a popular children's game. Though these and other games have places in cricket's ancestry, many of them remained popular even after cricket had arrived.

The beginnings of athletics can also be found in old England. Putting the weight and casting the bar—a forerunner of hammer throwing—were popular with the courtiers in Tudor times, while other events, including javelin throwing, were practised by ordinary people of the same period.

Tournaments and jousts survived from the Middle Ages to Tudor times. These were combats between mounted men, a joust being single combat, while a tournament involved many contestants. Competitors were required to swear an oath stating that they were taking part purely for sport, which has its modern counterpart in the Olympic oath. Somewhat similar to jousting, but not restricted to the nobility, was Tilting at the Quintain, in which a lance was thrust at a wooden target which, if not struck accurately, swung round and struck the tilter. This sport was practised both mounted and on foot.

Other old games, clearly the ancestors of modern ones, included Handball, which became Fives, but which is still Handball in America; Battledore and Shuttlecock, still a children's game, but developed by adults into Badminton; and Shovelboard, an elaborate game for the nobility consisting of sliding weights down a long table marked with lines, which is certainly the forerunner of Shove-Ha'penny.

### Knur and Spell.

Knur and Spell belongs to Lancashire and Yorkshire, and originated in a children's game called Trap and Ball.

The player uses a wooden club, the striking end of which, called the pommel, is shaped something like a bottle, though with a flat hitting surface; and he tries to hit as far as possible a small ball which he himself releases from a trap by means of a trigger. The ball, which is the "knur," was originally wooden, but later porcelain was used. It weighs half an ounce and measures 1 inch in diameter. The trap is the "spell," and consists of a small brass cup and a strong spring, which is kept down by the trigger. The fixing of the "spell" is an elaborate business requiring the use of a spirit level; and, when it is in position, a player is allowed ten minutes to adjust the tension of the spring. Players generally have their own "spells."

In some versions the ground is marked by pins placed 20 yards apart. This avoids the necessity of measuring each hit, as each 20 yards covered counts one point, each player usually having five consecutive hits or "rises." Experts can achieve distances of over 300 yards.

### Marbles.

Marbles is supposed to have been played in ancient Egypt, but its popularity in England, with adults as well as children, during the Middle Ages entitles it to count as an old English game. It is still played by adults as well as by children.

Marbles are often made of clay, but better ones are glass, and the best are pure marble. These are called "alleys" or "alley taws." There are several different games, but the main feature of all of them is the aiming of a marble at a target that is often another marble, but is sometimes an opening, by bowling or shooting it along the ground. In shooting, the marble is held between the thumb and forefinger, with the knuckle of the forefinger on the ground. The marble is then flicked away.

Perhaps the best-known game is Ring Taw, in which players shoot from one circle at marbles placed in another about 6 feet away. Fortifications and Increase Pound are games using con-

centric circles, the players shooting at marbles in each circle in turn: while Three Holes and Handers entail shooting at holes in the ground. Arch Board or Bridge Board involves aiming at arches cut in an upright board; and, in Die Shot, the players shoot at a marble on which a numbered cube-die is balanced.

### Pall-Mall.

Two London thoroughfares, Pall Mall and the Mall, are reminders that Pall-Mall was once popular.

It is often described as a forerunner of croquet, but it was really more like a form of golf, a game that arrived at about the same time, both having a common, if remote, ancestor in Paganica, a game introduced by the Romans.

In Paganica players walked across fields hitting a small leather ball at trees with a curved stick to see who could reach the target in the fewest strokes. It was played by country people, whereas Pall-Mall, which achieved rapid popularity in the seventeenth century, was a game for the nobility, though other people played simplified versions of it.

Pall-Mall was played in special alleys, sometimes half a mile long, and often surrounded by walls. A boxwood ball a foot in circumference had to be played down the alley in as few shots as possible, passing through a number of iron arches on the way. The player drove off as in golf; and, on reaching the arches, not only changed his club for the shorter more careful strokes needed, but

also put down a smaller steel ball instead of the boxwood one.

### Skittles.

An ancient game played in a special alley, level, about 12 yards long and 3 or 4 yards wide, skittles consists of throwing a flat-sided, wooden ball, weighing about 10 lb. and called a "cheese," at nine pins, each weighing 7-9 lb., arranged in a diamond formation 6-8 yards away, the thrower being allowed one forward step while throwing.

Scoring is either by knocking down as many pins as possible in a fixed number of throws or by knocking down thirty-one in the fewest possible throws. Still another method is to try to knock down the full set of nine in three or fewer throws.

Alternative games include one using only four pins, and Dutch skittles, in which a round ball is bowled, not thrown, and in which the centre, or king, pin must be hit first. This resembles the American game, bowling, which uses ten pins, the tenth having been added when "Ninepins" was made illegal because of the gambling on it.

### Stool-ball.

Yet another ancestor of cricket, stool-ball is still a popular girls' game. The wicket is a piece of board a foot square mounted on a pole 4 feet 8 inches high; the bat has a round striking surface; and the ball is rubber. Wickets are 16 yards apart, and ten balls constitute an over.

# Poultry and Pigeons

By Dr. W. P. BLOUNT

## ANCESTRY OF THE DOMESTIC HEN.

Perhaps the best question to ask in order to get an idea as to the place of the hen in nature is the old one about "which came first, the hen or the egg?" This is because a semi-scientific reply immediately puts one into the picture by recalling that birds are very closely related to reptiles; and it would not be too great a stretch of the imagination to suggest that it was probably a reptile's egg which really began the development of the class of animal we now call birds (*Aves*).

There are in fact fossils dating back to an era at least 50 if not 150 million years ago, of reptilian-birds; animals which can be considered intermediate between the true reptile and the true bird. Animals apparently developed from a reptilian framework, yet having "wings" covered by feathers, a very long feathered "tail," and "teeth." Over a period of hundreds of thousands of years there appeared the necessity for the reptile to adapt itself to flight—hence the growth of wings and, of course, the change from a horny type external skin to one consisting of feathers. Egg production is also a common feature to this group of animals, although of course reptiles are divisible into those producing true offspring (viviparous) and those laying eggs (oviparous).

In contrast with the eggs of fishes, those of the reptile and bird are covered by a hard outer shell to give protection against evaporation—a feature unlikely to occur in the case of eggs laid by fishes. One sees therefore a wonderful adaptation by nature—the fish swimming freely in water; the amphibian frog commencing life in water, passing through the tadpole stage to the frog proper, and ending its life on dry land. Thence to the reptile, at home both in the water and out of it, with its adaptation later to tree life involving the appearance of "flying" or perhaps only "gliding" reptiles. Finally, the development of birds as we now know them.

To-day therefore we accept the existence of *Archaeopteryx* the fossilised reptile-bird as being definitely related to the ancestry of birds generally. Amongst living birds we have those which have only a miniature breastbone and are therefore incapable of flight, e.g., the ostrich; and the remainder are the *Carinatae*—birds with a well-marked keel. And chief amongst the many Orders concerned in *Aves* (birds) are: (a) *Galliformes*, e.g., domestic fowl and turkey; and (b) *Anseriformes*, e.g., the duck and goose. It is worth noting that the pheasant and peacock, which belong to the same Order as the hen, may all suffer from certain common diseases, e.g., Black-head. As a contrast the duck tribe appear resistant to this ailment, and for all practical purposes they are also immune to the Fowl Paralysis complex.

## BRITAIN'S POULTRY INDUSTRY.

Poultry were for many years the hobby of the back-yarder, being valued for their brightly coloured feathers and general conformation. Our poultry industry developed through such fanciers, and there are now some millions of hens on general farms, but the fancier still exists, however, his interests being maintained largely by shows.

The poultry industry began because of demands by the housewife for eggs and table poultry, and her special requirements must always be given first consideration.

A study of poultry has shown that some are best fitted for egg production, others producing meat more economically, but dual-purpose breeds or crosses are also available. There are, therefore, three main aspects to our present poultry industry: (1) the pedigree breeder; (2) the commercial producer of eggs intended for the housewife and bakery; and (3) the rearer of table poultry intended for family and hotel or restaurant consumption. The fancier has success-

fully maintained the external appearance (conformation) of his different breeds, but it is only as a result of studies based on economics that we have discovered those breeds and strains best fitted for either egg or table poultry production.

The development of the industry to its present state, now comprising over 90 million head of poultry, has been achieved only by means of hatcheries, where thousands of eggs are received each week and incubation carried out in large, mammoth machines. The day of the broody hen has long since disappeared, except when very small numbers of chicks are being hatched. The domestic poultry keeper usually keeps half a dozen or more birds to provide eggs for his household, and a few cockerels may be reared for festive occasions. He is, however, not advised to undertake the breeding or rearing of day-old chicks unless well experienced in these subjects. His household scraps, bread, swill etc., form cheap feeds, but they are unbalanced, and should be supplemented by "High Protein" layers rations for good egg production.

Breeds.—For egg production the R.I.R. is our most outstanding breed, but there are many good strains of Light Sussex, Wyandottes, and Buff Rocks (among the heavier breeds), and Leghorns amongst the light breeds. Many cross-breeds are equally suitable, with certain light-heavy crosses outstanding in this respect, e.g., W.L. x R.I.R. "Hybrids," specially developed by new breeding techniques are also available, e.g., "Thornbers 101-404," "Gold Links, etc."

RHODE ISLAND RED PULLET.

For table poultry production the Light Sussex is ideal, because of its splendid conformation and plentiful supply of both breast and leg meat, also its white skin and legs. The housewife unfortunately has a prejudice against yellow-legged breeds, although the taste and quality of their meat is just as good as that from the white breeds. Lt. Sx. crossed with R.I.R., Br. Leg. or Ind. Game are very popular, also New Hamps. and N. Holl. Blue.

The pedigree breeder maintains his breeds in pure form, and is able to identify his chicks and relate them to their parents. His is an exacting task, for he is particularly concerned with the intricacies of fertility and hatchability. The pedigree breeder is not able to provide sufficient stock for sole use commercially, but as a result of his work pure-bred cockerels can be mated to non-

pedigree pullets and the resultant chicks used for commercial purposes.

LIGHT SUSSEX COCKEREL.

### SYSTEMS OF POULTRY KEEPING.

The tendency to-day is for poultry to be kept *intensively*, that is with no opportunity to get out on to grassland, and the three main systems are: (a) Hen Batteries; (b) Deep Litter; and (c) Hen Yards.

#### Hen Batteries.

Here birds have their own cages, which are arranged in tiers, usually three high, and each pullet has its own individual food and water trough. The birds can be seen separately at all times, and it is, therefore, possible to decide whether or not they are paying for their keep. They are free from attacks by foxes and rats, and do not suffer from those diseases contracted by running over infected ground, *e.g.*, Tuberculosis. Their main disadvantage is the initial cost of the cage which varies from 18s. to 24s. This is compensated for by their better average egg production and the opportunity this system gives to the poultry keeper for culling. (Culled birds are those which do not appear to be profitable.) There is also the fact that after laying for one year in batteries, pullets can be sold at a premium, for laying stock kept intensively in this way are fatter (internally) and their flesh is very tender. Hen batteries are not cruel, because the birds eat well, lay well, "talk" contentedly, and do not suffer from disease. Colds, Fowl Pest, and Laryngo-tracheitis are the chief infectious diseases. Mortality averages 13%. Culling 50-100%.

Twin-bird hen battery cages, each of which holds two birds, are becoming popular because of the considerably reduced capital expenditure. It is important that such birds are fed on dry mash *ad lib.* Bullying may develop in a few cases, but this can be avoided by selection of stock, or by the use of spectacles or de-beaking.

SWIFTS CAFETERIA HEN BATTERY UNIT.

Cafeteria hen battery cages in which the food and water troughs travel up and down or around

the cages are also marketed in this country. They are very labour saving, and one man can look after 2500 to 3000 birds on this system. It is important that the birds are given a minimum of fourteen hours' feeding time.

Special cages for domestic poultry keepers and for the keeping of bantams are sold, and the former can be arranged so that the birds are kept out of doors the whole time, but winter production will not be high unless specially good birds are chosen. Under B.O.C.M. laying-trial conditions at Stoke Mandeville egg production (forty-eight weeks) was as follows:—

	Average Egg Production: Team.	Highest Egg Production: Bird.
Ducks	191	320
Pullets	184	309
Bantams	108	220
Turkeys (100 days only)	60	77

Food consumption (pellets) per bird per day averages:—

Ducks	6-10 oz.
Pullets	4½-6½ oz.
Bantams	3-4 oz.
Turkeys	6-8 oz.

#### Deep Litter.

The deep-litter system, introduced recently from America, makes use of any intensive type poultry house; but the more insulation provided by the walls and roof of the building the better. The object is to build the litter higher and higher, during which process heat is produced by the decomposition of the droppings from the birds. This gives rise to some ammonia, but the heat also dries out the litter. In other words, the birds are kept dry and warm, but special ventilation is necessary to dispose of the moisture vapour and ammonia which are natural by-products of this system. It is very labour saving, and one

"ASHANCO" TYPE FIXED-EXTRACTOR COWL.

man can look after several thousand pullets, probably twice as many as kept in batteries. To maintain egg production, particularly in the winter months, a generous ration of feeding-stuffs is essential, and there should be from 4 to 6 in. of hopper space per bird. Where large numbers of pullets are kept in one house (*e.g.*, 750) an automatic feeder is economical as well as automatic water devices; and instead of using single nests a communal type nest—one per fifty pullets—is also very labour saving. Unless great attention is paid to the ventilation arrangements, the litter will get wet in the winter-time, and moisture will condense on the roof, iron girders, windows, or other cold surfaces. Egg production will not then be satisfactory, and to keep the birds occupied—so that they do not develop vices from boredom—supplementary feeds of pellets, corn, or greenfood are advisable.

Normally mortality is no greater than that of hen batteries, but should any infectious disease break out it will spread rapidly throughout the majority of the stock, and for every one hundred pullets involved one thousand eggs may be lost, which is of vital importance should such diseases occur during the high-priced winter period.

### Hen Yards.

The hen-yard system is really an adaptation of the deep-litter system to that of the old-fashioned semi-intensive method of keeping poultry. A small house (with a droppings pit and communal type nest) supplemented by a yard twice this size. As a contrast to the semi-intensive system, the yard is covered by straw, which is gradually built up throughout the winter months. Grain feeds can be scattered on top of the litter each day, but continuous dry-mash feeding is essential to help to prevent feather pecking and cannibalism. This is the cheapest system of housing layers, and many old farm buildings can be adapted for this purpose, but egg production is usually somewhat inferior to the other two systems mentioned.

The true *semi-intensive system* of housing birds, in which they have access to both a house and run, has become much less popular because of the incidence of disease; for maladies such as Worms, Coccidiosis, and Fowl Pox are liable to be encountered year after year with this method of keeping poultry.

### Colony Houses.

When poultry are kept on pasture in small (colony) houses this is sometimes termed the *extensive system* of poultry keeping, and in order to avoid any build-up of disease the houses are moved about 25 yd. each week. They are less satisfactory for winter egg production, and much time may be spent washing dirty eggs.

### Fold Units.

Fold units are an improvement over the use of colony houses, the birds being confined to small, portable, combined houses and runs, approximately 5 ft. wide by 18 ft. long. Each fold holds about twenty birds, and is moved its own length every day, and in this way the birds get fresh grass and exercise. Lighted "static" folds are very useful for improving winter egg production. Such portable units can also be used for breeding stock, but feather pecking, cannibalism, and dirty eggs must be avoided if the system is to be successful. Folds are best used on level ground, and the soil should be sand or gravel—not clay.

### Area Requirements.

On the free range (extensive) method of keeping poultry only about 75 to 100 birds are allotted per acre of ground, *i.e.*, about 60-70 sq. ft. per bird; whereas on the semi-intensive system 200 birds per acre is normal (20-25 sq. ft. per bird). In folds each bird has about 5-6 sq. ft., which is the same amount as that allowed for hen yards.

In deep-litter houses 3½-4 sq. ft. for heavy breeds and 2½-3 sq. ft. for pullets of the light breeds is usual, contrasted with 2½ sq. ft. for hen batteries. (In twin-bird batteries, of course, the area is reduced even further.)

These facts show how modern methods of housing have economised on ground (or floor space) without deterioration in health or loss of egg quality—provided that the food given to the birds is "balanced," *i.e.*, complete in vitamins, minerals, trace elements, etc.

## INCUBATION.

If the temperature surrounding fertile eggs is raised to about 100° F. and maintained there for about twenty-one days they will hatch, provided the eggs are "turned" several times daily and the humidity kept within certain levels. This in fact is what happens when a broody hen sits on fertile eggs, but for commercial purposes artificial incubation is preferable if only because mammoth machines have now been manufactured capable of dealing with thousands of eggs instead of a mere ten to fifteen as in nature.

### Broody Hens.

Broody hens, of course, are perfectly satisfactory for incubating small clutches of eggs, but they should be de-loused and de-wormed before use. They should also be tested against B.W.D. and tried out with pot eggs before being given fertile eggs. Heavy breeds are often broody, but non-broody strains are available. Light breeds seldom go broody; crossbreeds vary greatly.

Broodies require to be removed from their eggs only once daily for 15 minutes' exercise,

feeding, and watering. After hatching takes place the hen and her chicks are best kept in a coop for two to three weeks before being transferred to more commodious surroundings.

Incubators can be heated either by hot air, water, or electricity, and they are available in sizes capable of dealing with from 80 to 36,000 eggs. They should be housed in a room where there is good ventilation without draughts, and where the air can preferably be warmed to about 60° F. before circulating into the machines. Instruments for recording temperature and humidity readings are essential, because alteration to either of these factors may retard or

PARAFFIN-OIL-HEATED, HOT-AIR, SMALL-SIZE INCUBATOR.

improve the hatchability of the eggs set. Normally about 75-90 per cent. of all eggs taken from breeding stock are fertile, and an equal percentage of the fertile eggs will hatch. In the end, therefore, about 65 per cent. of all eggs set will hatch, of which about half will be cockerels and the others pullets. It thus takes three eggs to produce one pullet chick.

### Hatchability.

Hatchability is governed by breed factors and also by environment, and in this connection the most important single factor, apart from the actual incubation, is nutrition. It is the foodstuffs given to the breeding stock which must contain vitamins A, B<sub>1</sub>, B<sub>12</sub>, D<sub>3</sub>, and E, and minerals (calcium, phosphorus, manganese), since these are all known to affect the development of the chick embryo. Hatching is, of course, governed by the ability of the chick to emerge safely from the egg in order to live its own independent existence, and this automatically implies that it must have been free from defects such as "crossed beak" and that both the shell and its membranes are sufficiently "softened" to allow the chick to emerge at about the twenty-first day of incubation.

### Factors Affecting Incubation.

**Storage of Eggs.**—Hatching eggs are best stored broad end uppermost at 55° F.; if the temperature exceeds 80° F. incubation will start automatically. Freezing may do little harm but should be avoided whenever possible.

If stored longer than seven days hatching eggs should be turned daily, but hatchability will deteriorate the longer they are kept; in any case it is unwise to keep them longer than 10-14 days.

Humidity should be quite high—between 60 and 90 per cent. Eggs received by train or lorry should be allowed to stand for twenty-four hours before being set, otherwise there is a risk of "tremulous air cell" developing.

**Cleaning Eggs.**—Eggs should *not* be washed except using water at blood heat (105° F.) containing a detergent. Mechanical dry cleaning is generally preferred.

**Incubation.**—Be certain to run the incubator at the temperature recommended by the manufacturers—each make of machine may differ in this respect. In still-air machines the temperature at the top of the eggs is important, and if too high this leads to embryological deformities; low temperatures delay the hatch. In the event of

an electricity cut keep the incubator room warm (90° F.) but open the machine every half hour or so to get fresh air into it.

It is not necessary to cool eggs—this is only actually necessary in small machines for *turning* purposes. Cooling itself delays hatching, and is to be avoided.

Humidity is very important as follows: Papworth machines require 55 per cent. relative humidity; Stephens 55 per cent. in the setter and 75 per cent. in the hatcher (when the eggs are pipping); Western 55-60 per cent.; Mayfair 68 per cent.

If humidity is low it may lead to a parching of the membranes, which then offer a physical barrier to hatching. Too high a humidity is also wrong, because it interferes with embryonic development and can cause death-in-shell.

Correct *turning* of the eggs during incubation is very important, as it imitates a physiological process carried out by the broody hen herself many times each day. It prevents the embryo from "sticking" to the inner shell membrane, and also makes certain in small machines that the temperature of the egg is equally distributed. Improper turning is believed to be one important cause for chicks finishing with their heads at the small end of the egg at hatching time. Hatching eggs should be turned in small machines at least twice and preferably three times in twenty-four hours; in Mammoth machines they may be turned each hour mechanically. It is not advisable to turn eggs during the three to four days immediately prior to hatching.

The Ventilation of the incubator room is vitally important, and as much fresh air as possible should be circulated—to supply oxygen and to remove carbon dioxide and moisture—without creating draughts. This air should also be warmed, if practical, to 60° F. Consideration must also be given to removing the foul air by outlet cowls or vents at the top of the room. Incubators should not be placed in a corner of a room nor up against one of its walls, as this impedes air circulation.

Nutrition of the Breeding Stock.—Unless stock cockerels and pullets or hens used for breeding receive a balanced diet, hatchability will be poor. Firstly, they should not receive large quantities of bulky food such as swill, Tottenham pudding, or steamed potatoes. Secondly, their diet should contain at least 3-4 oz. of "breeder's" pellets or mash, rich in vitamins; together with 1 oz. of whole grain. (Unnecessary if the breeder's ration contains vitamin E.) Recently a new vitamin —B<sub>12</sub>—has been shown to be essential for hatchability, but as it is present in fish-meal and dried skimmed milk, etc., unless a vegetable diet alone is being used it will be present in many diets. Concentrates of B<sub>12</sub> are now marketed, e.g., fish solubles and antibiotic residues.

**Candling.**—The method of testing eggs for fertility is known as "candling," and it can also be used for the determination of egg faults. The eggs are taken to a dark room or cupboard, where they are subjected to the bright rays of an electric lamp. Hatching eggs may be tested in bulk by lifting the trays over a special table with the electric light beneath it; the poultryman then marks the infertiles, which he subsequently removes. In the case of fertile eggs a small dark area can be seen as early as the fourth day, but candling is normally carried out on the seventh, tenth, or eighteenth days. In the case of infertile eggs they remain clear because of the lack of development of the embryo chick. When fertile eggs are tested on the eighteenth day the whole of the egg is dark except for the air space.

**Fumigation of Incubators.**—Due to the fact that large numbers of disease-producing germs may develop in eggs during incubation, and also because the "fluff" from newly hatched chicks may also be heavily contaminated with germs, it is important that incubators are thoroughly disinfected immediately after each batch of chicks passes through them. The common method is to add 1½ oz. of liquid formalin to ½ oz. of potassium permanganate crystals (for each 100 cu. ft. of air space). A violent chemical reaction takes place, liberating large quantities of formaldehyde gas, which, however, is more effective as a disinfectant if the interior of the incubator is humid and damp. All exits should be sealed for one hour. Poultrymen using this method for hatching eggs soon after they go to the incubators may prefer to use double the dosage.

#### Sexing Day-old Chicks.

The crossing of certain breeds, e.g., R.I.R. cock × Lt.Sx. hen, results in chicks the colouring or pattern of whose down at birth readily separates them into two groups, male and female. This is termed sex-linkage, and the basis for such matings provides an interesting study for students of animal breeding. In general, pure-bred chicks can only be sexed by hand (Japanese system) or by means of an entirely new method, demonstrated in this country for the first time at the 1951 Dairy Show. Older chicks, aged four to ten weeks, can be sexed as soon as they show distinctive sex characters—e.g., by the size of their comb and wattles, the shape of the bird's head and shanks, and also by the appearance of the neck, saddle, or sickle feathers.

#### CHICK REARING.

To-day very few chicks are reared under broody hens, partly because broodies are usually only available during a limited period of the year and also because unless chosen very carefully they

SINGLE-TIER TABLE BROODER FOR CHICKS.

may spread certain diseases to their chicks. More particularly, however, because to rear 100 chicks would require at least half a dozen broody hens, and these would not be easy to find at short notice, nor would they be easy to manage. Modern methods are such that 100 chicks can be reared to eight weeks of age on the floor of a room 15 ft. x 12 ft., but in tier brooders such a room might hold over 1000 chicks.

#### Requirements.

Artificial heat, food, water, bedding, and good ventilation provide the essentials for chick rearing, but the skill of the poultryman is an equally important factor. Day-old chicks can be purchased to-day in large or small numbers, suitably sexed—cockerels for table poultry and pullets for egg production—at a few shillings each, and as soon as they are received they should be put under an artificial foster-mother—a *hoyer*. Electric or infra-red ray lamps are very popular nowadays, because they need so little attention yet provide an adequate reserve of heat. The temperature at the level of the chicks' heads should be about 95° F. during the first week; thereafter it can be reduced gradually until the chicks are free from artificial heat by four weeks of age (five weeks in winter-time). Oil-heated hovers of circular and pyramidal patterns are equally successful, but require rather more attention, both as to the supply of fuel and also for dealing with the foul air.

#### Ventilation.

No matter what system of brooding is adopted, the air in the room or compartment should be kept quite fresh, and if it feels muggy or creates a sensation of headache in the attendant something is wrong. Too often the amateur keeps the atmosphere too hot and also too dry—it is only under the hover that the air needs to be heated, elsewhere it can be quite cool, so long as there are no draughts. Cold air stimulates feathering, and also increases the appetite. The adjustment of windows is very important, and requires constant attention because of climatic differences from day to day; special attention must also be paid to this work at night-time when strong winds or gales may suddenly appear.

#### Equipment.

Young chicks have little initial sense as to their ability to get warmed up under a hover, but they soon learn this by instinct if given assistance. For this purpose a metal or cardboard surround (15 in. high) about 3-4 ft. in diameter is invaluable during the first few days. Its use prevents chicks from straying, and in this way they quickly learn where to find heat, food and water.

FOOD HOPPER FOR CHICKS.

Food Hoppers should be such that chicks do not walk over the food, nor foul it with litter, etc. As soon as possible they should be raised on blocks of wood, or the feed will be constantly covered by litter scratched there by the chicks. Fresh supplies of food should be used daily, and sufficient hopper space allowed so that each chick has ample opportunity to feed. If wet mash is being given wooden food troughs are preferable to those made of metal.

Water Troughs must be large enough to hold a full day's supply of water and also be capable of being cleaned thoroughly. Water troughs should not be so large that day-old chicks can get into them, or they may drown.

For day-old chicks an inverted 2-lb. jam jar over a large saucer can be used in an emergency,

but portable, inter-locking, two-piece water fountains are preferable. If skimmed milk is being used the waterers should be sterilised three times a week—sour milk soon clots, and then does not flow freely.

#### Housing.

Considerable skill is required when chicks are to be reared out of doors, and for this reason they are best brooded under hovers, on solid floors; or in tier brooders. By eight weeks of age, however, when they should be fully feathered, they can be taken outside, and one of the best pieces of equipment for rearing pullets or cockerels is the well-known Sussex Night Ark.

SUSSEX NIGHT ARK (YOUNGS OF HORLEY).

#### Litter.

For bedding purposes a variety of materials are available, but peat moss, chopped straw, or wood shavings are often preferable to chaff, coffee husks, or sawdust. A layer  $\frac{1}{2}$  in. thick should cover the floor, but its renewal will depend upon the risk of Coccidiosis, and unless replaced every day an anti-coccidiosis drug may require to be used in the feed or water. Some poultrymen are successful in building up the litter to a depth of several inches (as the chicks grow older), but considerable skill is required, or it will get damp and soggy and become a source for disease. Musty or mouldy samples of bedding materials should be avoided, because they may lead to an outbreak of Aspergilliosis.

#### Feeding.

The system and method of feeding day-old chicks is vital to their success. The first feed should be given at floor level, below or near to the hover. A sheet of cardboard, or part of a feed bag, can be laid on the floor and the mash, crumbs, grain, wet mash, or whatever feed is being given scattered over it as soon after the chicks have settled down as possible. It is a completely mistaken idea to deprive chicks of their first feed for two to three days, and the earlier they get it the better. A few ounces of food scattered over the floor in this manner will occupy the chicks during their first day or two, until in fact they have learned where to find their ordinary food troughs. (Feeds of wet mash, however, must be given four to five times a day, whereas crumbs can be left on the floor indefinitely—the chicks will soon discover and eat them all up.)

#### Note.

Even in the case of chicks being reared on wire floors it is still a good plan to give them an early feed, on paper, at floor level. After the first day more feed can be given on egg flats for example; this encourages the chicks to forage, during which period they will soon discover the site of their proper feed troughs.

Amongst the feed should be scattered some coarse sand or fine flint or gravel grit, because although this may not be actually necessary for grinding up the food in the gizzard, it will prove invaluable should chicks attempt to eat some of their litter.

Some poultrymen insist that the first feed for their chicks shall be grain—groats, cut wheat, or maize grits—others prefer dry bran, but both practices are wrong. The feed should be "balanced," from both the growth and health standpoints, and this means a properly prepared ration which can be given as crumbs or mash—wet or dry. The greater the palatability of the feed (assuming it to be balanced) and the more food eaten the quicker the growth rate of the chicks. The following data are taken from Stoke Mandeville:—

	Weights.		
	Chicks (Lt.Sx. Cockerels)	Ducklings Aylesbury (mixed sexes)	Turkey Poults (A.M.B.)
Day-old	1½ oz.	1½ oz.	1-8 oz.
1st week	2½ oz.	5 oz.	3-7 oz.
2nd week	4½ oz.	13 oz.	6-1 oz.
3rd week	7 oz.	1 lb. 10 oz.	9-3 oz.
4th week	11 oz.	2 lb. 10 oz.	13-17 oz.
5th week	1 lb.	3 lb. 9 oz.	1 lb. 2-8 oz.
6th week	1 lb. 5 oz.	4 lb. 8 oz.	1 lb. 9-4 oz.
7th week	1 lb. 10 oz.	5 lb. 7 oz.	2 lb. 1-9 oz.
8th week	2 lb.	6 lb. 2 oz.	2½-3½ lbs.

Weighing Scales are necessary to check the progress of one's chicks, because a steady growth rate is essential for the successful rearing of poultry, no matter what the species. They should preferably be capable of weighing between 1 oz. and 10 lb., for they can then be used on any bird between day-old and four months, and they will be equally valuable for weighing food. If weights are known for both growth rates and the amount of food consumed, then a "feed conversion" factor can be obtained.

Feed Conversion is related to the particular strain of bird; the nature of the ration; the construction of the feed hoppers; the weather and housing. At 3-4 lb. body weight the conversion rate will be about 2.9-4.5.

#### Food Consumption.

Assuming that poultry are being fed on meals and not receiving swill, cooked potatoes, or other bulky feeds, their needs can be calculated from the following table:—

	Chicks.	
	(1).	(100).
1-7 days	1½ oz.	9½ lb.
1-14 days	5 oz.	31 lb.
1-28 days	1½ lb.	1 cwt.
To 8 weeks	6 lb.	5½ cwt.
To 16 weeks	27 lb.	1 ton 4 cwt.
To 26 weeks	35 lb.	1 ton 11 cwt.
1st Laying Year	1 cwt.	5 ton
	90-140 lb.	4 tons-6½ tons

In the case of "light" breeds these figures can be reduced by one-fifth to one-eighth, and for the heavy crosses increased similarly. Where grain is being fed this should not replace more than 25 per cent. of the chick, 33 per cent. of growers', or 50 per cent. of the layers' rations.

## POULTRY NUTRITION.

### Rations.

To-day all feeding-stuffs are off-ration, and coupons are now non-existent. Manufacturers of compound animal feeds usually offer the following balanced rations:—

1. "Baby Chick," intended for use from day-old to about four to six weeks of age; complete and balanced in every way, such feeds do not require any grain, fresh greenfood, skimmed milk, or limestone grit. Baby chick rations are often available in two forms, i.e., as mash, and crumbs—the latter is just as palatable as wet mash, but does away with the extra labour involved in preparing it. The continuous *ad lib* method of feeding by which the chicks help themselves is commonly practised, because it satisfies the appetite and saves labour as well.

2. "Growers'" Rations contain less protein and fewer vitamins than those intended for young chicks, and are given to stock aged six to twenty weeks. "Growers'" rations are complete in

themselves, and if grain is to be fed in any quantity, then a poultry "grain balancer" feed should be used instead. This is available as mash or pellets (½ in.), and although the former is often given *ad lib*, pellets are usually restricted to 1-3 oz. per bird per day.

3. "Layers'" Rations are also complete, and it is a mistake to dilute them with grain, because egg production will then fall in proportion to the amount of grain fed. (See next para.)

4. "Poultry Grain Balancer" Rations are necessary because grain itself is unbalanced—being rich in energy, and low in protein and vitamins, therefore, a special balancing ration is desirable. But not more than 40-50% of the layers' ration should comprise grain. For growing stock more can be used to retard maturity. All laying stock require limestone or oyster-shell grit to supplement their ration—about 1 teaspoonful daily. Also flint grit once a month.

5. Hen Battery Mash and Pellets (½ in.) are specially prepared for use by stock kept in hen battery cages, and they, too, are best used liberally and without any addition of grain. Hen Battery Mash can also be recommended for use by stock housed intensively, e.g., on Deep Litter; but pellets are not recommended for continuous feeding. (This is because with pellet feeding a full crop is obtained quickly, and the birds, having little to do, look around and may start pulling out one another's feathers. This leads to unsightliness and also occasionally to actual cannibalism.) De-beaking or the use of spectacles will prevent many cases of feather pecking or cannibalism.

5. "Breeders'" Rations (mashes or pellets) are compounded with a view to supplying the requirements of birds whose eggs are going to be incubated. They supply additional vitamins and minerals which pass over to the day-old chick *via* the yolk sac. If an ordinary layer's ration is used instead, an increased number of "dead-in-shell" may show characteristic defects.

6. "High Protein" Meal is prepared for the exclusive use of domestic poultry keepers. It is richer in proteins than other poultry feeds, because it is intended to "balance" household scraps, swill, and allied feeds. "Balancer Meal," available during the war, did not contain any added salt, but "High Protein" feeds which have replaced it contain 1% salt.

7. Grit.—There are two types of grit. (i) *Insoluble*—flint, granite, gravel, etc.—required by poultry of all ages, at approximately monthly intervals, if they are being given grain, grass, or other feeds which require grinding in the gizzard. (ii) *Soluble*—limestone, oyster, etc.—required by layers only if balanced rations are otherwise being fed. (Mashes, crumbs, and pellets break down in the gizzard satisfactorily without grit.) An excess of grit may pass through the gizzard to cause irritation of the intestines.

### Digestion in the Hen.

Unlike most farm animals, poultry swallow their food whole. It passes through the crop and proventriculus (stomach) to the gizzard, where it undergoes slow disintegration under the powerful contractions of its dark-red muscles coupled with the presence of hard, flint-like pieces of grit or stone. As soon as the gizzard is full all succeeding feed is stored in the crop—at the base of the neck—where it is warmed, softened, and acidified by lactic and other acids formed as a result of bacterial fermentation. The semi-fluid foodstuffs passing from the gizzard to the small intestines are part digested, but intestinal juices and those from the pancreas complete this process prior to its assimilation and transformation into meat and eggs. (Bile assists the emulsification of the intestinal contents, but does not supply any digestive ferments.) The semi-fibrous residues which remain pass quickly through the succeeding portions of the digestive tract and leave the body later as droppings—tinged with a whitish "cap" so well known to the poultryman. This latter consists of compounds of uric acid which are being continuously excreted *via* the kidneys.

A hen passes eight to ten lots of faeces each day, one such mass coming chiefly from the blind guts. It is bright in colour, usually yellowish-brown tinged, and of a semi-liquid consistency. It is free from fibrous material, but very evil smelling.

and sometimes it contains a number of small Heterakis worms ( $\frac{1}{4}$ "– $\frac{1}{2}$ " in. long).

### Feeding Poultry on the General Farm.

**Chicks.**—It is vital to give chicks the best possible start in life, and this means using a special chick ration from day-old. The nutritional requirements of chicks are complex, but their actual food consumption is low and, therefore, for both these reasons it is a really sound plan to use a well-balanced chick feed containing animal and vegetable proteins, vitamins A, B, D, and E. Since chicks eat very little food up to 8 weeks the cost of feeding a special, balanced ration is well worth while.

Do not try to economise by using home-grown grains at this period, because they are somewhat unbalanced and better reserved for the later growing stages. In other words, feed a balanced chick ration as long as possible, and do not dilute it even with skimmed milk, because this upsets the balance of the other ingredients.

**Growers.**—As a contrast, growing stock aged six to twenty weeks can be given a more bulky ration, and grain can then be used freely, also steamed potatoes, Tottenham pudding, etc. Wheat is the best grain, but oats or barley are also quite satisfactory. If home-grown grass-meal is available 5 per cent. can be added to the ration, providing it is of good colour and quality.

As regards special foods a grower's pellet or mash is best if little grain is available, but if there is a lot, then a "grain balancer" ration is better. Broadly speaking, one should give 1 part of grain balancer mash or pellets to 2 parts of grain in the early stages, then half and half when the birds are about four months old, and at point-of-lay pullets should be given two parts of grain balancer to one part of grain.

**Laying-Stock.**—The feeding of layers is simple, but the ration must be balanced for economic egg production. It is not just a question of feeding the birds and hoping for the best, it is important that a layer receives 4–5 oz. dry matter containing not less than 15–16 per cent. of good-quality protein. This can be given in the form of pellets or mash; the latter may be fed dry continuously all day long; or as a wet mash 2–3 times daily. For use in hen batteries the ideal ration consists of 4½–6 oz. of hen battery pellets. To achieve the right proportion of essential ingredients is vital, farmers are advised therefore to consult a nutritional expert if they intend mixing their own meals.

**Table Poultry.**—Special rations are now also available for table poultry production. They contain added proteins and vitamins and special growth factors such as antibiotics like penicillin; also anti-coccidiosis agents like the "sulpha" or "nitro" drugs; they are higher in energy and lower in fibre than ordinary chick rations, and as such have a better feed conversion, i.e., only 3–3½ lb. feed are required per 1 lb. liveweight gain.

**Breeding Stock.**—The feed for breeding stock must support the bird for its maintenance and egg-production requirements, and it must also supply nourishment for the resultant day-old chick. This can be supplied by 4–5 oz. breeders' pellets (or mash) plus 1 oz. grain. Such feeds should commence 3–4 weeks before the hatching season starts. For those poultry breeders keeping their stock intensively (on the deep-litter system) 3 oz. of breeders' mash, ½ oz. of grass-meal, and 2 oz. of wheat is an excellent combination. Fresh greenfood is also useful but not essential.

### EGG PRODUCTION.

Most domestic hens of the improved breeds—R.I.R., Lt.Sx., W.W., Buff Rock, Leghorns, etc.—are capable of laying 150–180 eggs per bird during their pullet year, provided they receive a balanced diet and are managed with common sense. As a fact, many families have been bred to lay from 200 to 250 eggs per year, and just as there are a few cows which can be expected to give 3000 gallons of milk, so there are occasional hens which lay 300 eggs in a year.

Laying stock should receive as few checks as possible during their rearing stages, which implies

that they will have remained free from B.W.D., Coccidiosis, etc., and that they will have received a good, generous diet and will not have been unduly exposed to severe climatic conditions.

Chicks hatched in the spring of the year start laying about twenty to twenty-six weeks later, the light breeds laying earlier than "heavies" by about two to four weeks. The ovary starts to develop actively about one month before production commences, and the associated oviduct becomes equally active, increasing in both length and diameter. Both these functions are governed to a large extent by hormones, formed by certain small glands, e.g., the pituitary gland at the base of the brain, the thyroid gland, etc. In this connection light plays an essential part—see p. 959.

There are no obvious signs that laying is a painful process, but in a few instances slight cloacal haemorrhage occurs at the time the first egg is laid, and sometimes this is known to coincide with the passage of a much larger egg than normal. The first twelve to twenty-four eggs are generally the smallest, weighing on the average about 1½ oz., but once maturity is reached, egg size remains relatively constant, averaging about 2 oz. in most cases. But even larger egg strains of poultry have been developed, by selective breeding, and in such cases their eggs will weight 2½ oz. and over. The production of large eggs is to be discouraged unless a cash premium is available.

Egg size tends to fall in the hotter, summer months when day temperatures exceed 75° F., and shell texture also deteriorates.

When pullets first come into production not infrequently they lay soft-shelled or double-yolked eggs, but neither should be considered seriously, as in most cases normal eggs quickly follow.

**Double-yolked Eggs.**—Should the ovary release two yolks simultaneously or separated by only a very short interval, this will result in the formation of a double-yolked egg; whereas if the yolks are liberated at an interval of several hours, two eggs are likely to be laid during the succeeding twenty-four hours.

**Cracked and Soft-shelled Eggs.**—Cracked eggs may result from: (i) a defective diet, the rations being deficient in calcium (lime), phosphorus, or vitamin D; (ii) a weakness of the oviduct; or (iii) local damage, as from the use of a faulty nest-box or badly constructed hen-battery cage.

When soft-shelled eggs appear this probably represents an over-activity of the muscles of the lower oviduct—the "egg" being expelled before the shell has had time to be laid. If, however, a succession of soft-shelled eggs are laid by the same bird, this probably represents a constitutional weakness, and such birds should be culled.

**Mis-shapen Eggs.**—These are proof that the oviduct is functioning peculiarly, and in a few cases they are associated with the presence of a tumour or other obstruction involving a ligament of the oviduct. Therefore the repeated laying of such eggs indicates that such a bird should be removed from the flock.

**Annual Production.**—Egg production falls as a bird gets older, and the following figures give an indication as to what may be expected from hens as they get older:—

Pullet Year . . . . .	200
Second Year . . . . .	160
Third Year . . . . .	125
Fourth Year . . . . .	100

**Composition of Eggs.**—The increase in albumin which occurs in large eggs can be seen from the following tables:—

Egg Size.	Albumin.	Yolk.	Shell.
1½ oz. . . . .	57%	32%	11%
2½ oz. . . . .	62%	27%	11%

The colour of the yolk is dependent almost entirely upon the diet, and if the latter is devoid of greenfood and maize the resultant yolks will be almost white. In general, the more greenfood the deeper the yellow-golden colour, but in some cases believed to be due to certain weeds, reddish orange colours may occur. Green yolks may be due to feeding an excess of acorns or using certain samples of cottonseed meal, or from too much herbage.

**Egg Production—Strain Variation.**—When a farmer buys a batch of pullets he expects them to lay fairly consistently, but due to the fact that breeders have not been able to standardise their stock by ordinary selective methods, there is a considerable variation in their egg production. The following example is taken from eighteen half-sister (Black Leghorn) pullets over a test period lasting forty-seven weeks:—

142	162	174
178	123	180
211	163	266
200	184	48
217	218	172
121	215	210

Thus, although the average egg production per bird was 177, the variation was from 48 to 266. Hybrid stock (e.g., Thornberrns "101") and incross-breeds may be expected to show a higher average production with less individual variation.

**Value of Daylight for Egg Production.**—Farmers do not always appreciate that there is a minimum amount of daylight required by nature as her normal stimulus to egg production. Experiments at Stoke Mandeville have shown that where daylight is restricted, as by the absence of suitable windows or roof-lights, such pullets will each lay sixteen eggs less during the winter months compared with sister pullets kept in hen-battery cages facing the daylight. At the Poultry Research Centre, Edinburgh, increased egg production has resulted from the provision of standardised light, humidity, and temperature, e.g., 12 hours light, temp. 65° F., humidity 60 per cent. (relative).

**Value of Night Lighting.**—In winter when there are only eight hours of daylight, egg production can be stimulated if electric or other artificial lighting is used to extend the period of daylight to about fourteen hours. Using 60-watt lamps placed one per 100 sq. ft. of floor space, suspended about 6 ft. above the floor, should give the right degree of light. Coloured lights are not superior to incandescent lighting. Recent experiments have shown that the use of 1500-watt lamps for 40–60 seconds daily also acts as an efficient stimulus to the ovary—the light effect being *via* the eyes and pituitary gland at the base of the brain.

### TABLE BIRD PRODUCTION.

Poultry for human consumption readily fall into several classes:—

(i) Poussin (weighing 1½–1¾ lb.) are required for the hotel trade. Double-poussins weigh 2 lb. They are aged six to nine weeks, and should have been fed on Baby Chick mashes or "crumbs," plus antibiotics.

(ii) Roasters (weighing 2½–4½ lb.), for both the housewife and restaurant trade, can be carved into four or six portions. They are aged ten to sixteen weeks, and will reach the required weight all the more quickly if they receive "chick" rations throughout. A special term "Broiler" (not boiler) is used to describe the very youngest of roasting birds weighing 2½–3½ lb. Such birds can be produced in 10 weeks on 10 lb. of feed, if antibiotics are used.

Heavy-weight roasters of 6 lb. or more are occasionally available, usually as *Capons*, but they are less economic to produce, and few housewives can afford such birds except for special occasions. These luxury birds are obtained by caponising—surgically or chemically—and are aged from four-teen to twenty-six weeks.

*Capons* are male birds deprived of their testes in order that they may fatten quickly. The operation is carried out at about eight weeks of age, but "slips" occur, and a few cockerels may even die. Six months later such capons will weigh 2–3 lb. heavier than ordinary cockerels, i.e., about 8–10 lb. apiece.

**Chemical Caponising** by means of implants (15 mgm.) of female sex hormones (stilboestrol, hexoestrol, etc.) is rapidly becoming popular, because it is cheaply and easily carried out, causes no deaths, few slips, and the results are positive in 4–5 weeks' time, when the injected birds will be considerably fatter than normal.

Such birds stop crowing, go pale in the comb, and lose their combative instincts. Internally there are heavy deposits of fat lining the abdomen and also between the muscle fibres. Older cocks aged one to three years can be tenderised by being given two such implants at six-week intervals, the first to be given three months before killing.

(iii) Boiling Fowl are of two classes: (a) specially fat, tender, yearling pullets (5–7 lb.), taken direct from hen batteries, where their special environment will have meant that they will not have been subjected to exercise (which toughens the meat). A premium of about 2d.–4d. per lb. can usually be obtained in favour of such birds at the end of their first laying season. (b) Hens of all other classes and ages—these are less tender and, if taken from free range, are usually lighter (3½–5½ lb.).

(iv) Ducklings for roasting purposes are young, succulent, and tender, and weigh from 4½–8 lb. at eight to ten weeks of age. Older ducks are seldom profitable unless special circumstances demand their retention to about 15 weeks of age.

(v) Turkeys for roasting at home vary in weight from 6–15 lb.; the females weighing about two-thirds that of the male. Older birds are only of use to the hotel trade. The world's heaviest turkey weighed 65 lb.

(vi) Geese, like turkeys, are mainly fattened for the restaurant trade, and weigh at nine months 10–20 lb., but their popularity is not increasing in spite of the fact that they eat large quantities of grass and very little "concentrate."

### DUCKS.

Ducks have many advantages over chicken—they grow faster, weigh heavier, lay more eggs, and suffer from fewer diseases; yet they are not as popular as might be expected—why is this?

Firstly, they may not make a profit, because there is sometimes a consumer prejudice against eating duck eggs, but like eating pork in a month without the letter "r" in it, this prejudice is more fanciful than real. It arose no doubt because there have been occasional deaths or illnesses due to the consumption of *Salmonella*-contaminated eggs; but there are also other and more important sources of this type of infection.

Secondly, the egg production of the table breeds of ducklings—as opposed to the layers—is very low, and therefore there is a very seasonal trade in ducklings, except in the case of *Penines* now being hatched the year round.

**Breeds.**—As layers the Khaki Campbell breed is supreme, many strains laying upwards of 275 to 300 eggs per year. The *Pekin* is an excellent dual-purpose breed, some strains of which are also good layers; and there is also the *Indian Runner*. But for table work the *Aylesbury* is easily the heaviest and most rapidly growing breed in the country, but its poor egg production is against its expansion. The new *White Penine* breed is nearly as good as the *Aylesbury* for table purposes, and is also an improved layer. Average weights are: Khaki Campbells 4 lb.; *Indian Runner* 4½ lb.; *White Penines* 5–5½ lb.; *Pekins* 5½–5¾ lb.; *Aylesburies* 5½–7 lb. at 8–9 weeks.

**Rearing.**—Ducklings are easy to brood, and where electricity is available infra-red-ray lamps are ideal for the purpose. They can be taken off heat at two-and-a-half to three weeks of age—at least one to two weeks earlier than chicken. Although they need plenty of drinking water, a pond or stream is not a necessity, and puddles should always be avoided, as they may harbour disease parasites. Ducklings grow best on pellets or crumbs given *ad lib*, but wet mash is also popular. By four weeks of age ducklings can be given bulky feeds containing steamed potatoes swill, Tottenham pudding, etc. They will reach their second feathering stage by ten weeks of age, and should be killed off for the table before this period is reached, otherwise plucking and stubbing will be difficult. Wet plucking is not satisfactory for ducks, and even dry plucking machines require to be followed up by very careful hand stubbing—but the feathers are valuable, to-day's price being 7s. per pound. (Hen feathers fetch only about 1s. 8d. per pound.)

As table ducklings reach 6 lb. by eight to nine

weeks of age compared with sixteen to eighteen weeks for cockerels, they should be cheaper to produce, but day-old ducklings at 3s. apiece cost three times that of cockerels. In proportion there

AYLESBURY DUCK.

is less meat on a duck, and for these reasons it falls into the luxury class of table poultry.

**Diseases.**—Ducks do not suffer from Coccidiosis, Gapes, Newcastle Disease, Fowl Pox, or Fowl Paralysis, but they do get Salmonella infections (Keel Disease), diseases of the reproductive and excretory systems, and also tumours.

*S. aertrycke* infection is responsible for very heavy losses in young ducklings aged three to fifteen days; and survivors may lay contaminated eggs for long periods. Eggs from such birds may be the cause of food poisoning, but it would not occur if attention was given to avoiding the consumption of raw eggs, or of boiling them for ten minutes. This will destroy any Salmonella infection present. (Table ducklings are rarely if ever the cause of food poisoning.) Attention should always be given to collecting duck eggs in as clean a state as possible, and if they are dirty they should be cleaned in hot water (110° F.) containing a detergent, e.g., a quaternary ammonium compound; or one containing chlorine.

### TURKEYS.

Whereas an average fowl will weigh from 5 to 7 lb. at maturity, a turkey hen will weigh more than twice as much; male birds ("stags" or "toms") weighing from 20 to 35 lb. apiece.

These large birds were ideal for family parties at Christmas-time thirty to forty years ago, but with money now scarce, smaller families, and small ovens, the day of the really large turkey has passed, except for the restaurant trade. To-day most housewives demand a bird weighing 8-15 lb., and this favours their use of hen turkeys.

**Breeds.**—For breeding pens one stag to seven hens is commonly practised. The most popular turkey in Britain has been the *American Mammoth Bronze* (A.M.B.), females weighing 14-18 lb. and males 18-24 lb. A peculiar sheen to many of the feathers give the bird its "bronze" character.

**Broad Breasted strains** (B.B.B.) carry additional breast meat and weigh 15-30 lb. at seven to eight months of age. These have recently been imported from North America.

The *Norfolk Black* is an excellent bird for the general farmer, being lighter than the A.M.B., but with a particularly nice, plump breast.

The *British White* turkey (also known as the "Austrian White") is almost as heavy as the A.M.B., but its feathers are more valuable. They are very popular in the south-eastern counties. A new white turkey recently imported from America, the *Beltville Small White*, matures two to four weeks earlier, and weighs about 8-15 lb. Its economical qualities are making it very popu-

lar, particularly its good egg production and better hatchability.

The demand for smaller turkeys has led to the production of "Baby" turkeys ("Broilers") aged 10-16 weeks, weighing 4-10 lb. Any breed can be used, but at this age they often lack fat under the skin and are therefore considered by the trade to be "unfinished." Chemical canapising may overcome this objection.

**Rearing.**—Turkeys are not difficult to rear if given: (i) a correctly balanced diet right from hatching; (ii) plenty of heat under the hover (95° F.); they should be (iii) kept away from all other poultry; and (iv) preferably reared intensively for the first eight weeks.

AMERICAN MAMMOTH BRONZE TURKEY.

The first feed should be placed on a piece of coloured paper laid over the floor under the hover; a scattering of flint grit is also necessary, and the drinking-water must be close at hand. Turkey Starter rations must be kept in front of the poults all day long, and no grain or greenfood should be given for the first six to eight weeks. By this time they will weigh from 1½ to 3 lb., and their teething troubles will be over, except for diseases such as Blackhead and Coccidiosis. The new drug "Entramin" is specific for Blackhead, and Coccidiosis can be controlled by the use of sulphadiazine. A separation of turkey poults from domestic hens commonly avoids serious losses from Worms, Gapes, Fowl Pox, and Blackhead.

### GEESE.

Few geese are kept commercially, although many farmers keep half a dozen for their own use at Christmas-time. They eat large quantities of grass, and require little extra feeding beyond that which can be supplied by home-grown grains.

**Breeds.**—In general, the larger the breed, the smaller the number of eggs laid by the females, thus the Chinese may lay 60 or more eggs, compared with only 20 by the Toulouse. The *Grey* and *White Chinese* are, however, less popular because, although of attractive external appearance, their flesh is dark, and they are very noisy. Among white-feathered breeds the *Roman* and *Emden* are favoured, as is the grey *Toulouse*; but many farmers prefer a crossbred, e.g., *Emden* × *Toulouse*; or *Roman* × *Toulouse*. The very rapid growth rate of geese can be seen from the following results at Stoke Mandeville (1954):—

Weeks.	Chinese.	Roman.
1	8-8 oz.	9-9 oz.
4	3 lb. 1 oz.	4 lb. 5 oz.
8	7 lb. 0 oz.	8 lb. 8 oz.
12	8 lb. 15 oz.	10 lb. 6 oz.
14	9 lb. 6 oz.	11 lb. 12 oz.

Although when mature geese weigh from 15-30 lb., they are much less popular than turkeys,

partly because they are lacking in flesh (on the breast), also because the flavour of the meat is less palatable.

Breeding stock are not chosen until they are 2-3 years old, but they may be used for upwards of 5 years. For light breeds one gander to 4-5 females is practised; for heavy breeds one gander to 2-3 females. Geese often mate for life, and it may be difficult to re-mate them if breeding pens are broken up.

Incubation takes twenty-eight to thirty days, and from ten to twelve eggs may be set under a goose, but an ordinary domestic hen can only take about four—which must be turned daily by hand. They should be sprinkled with warm water during the latter half of the incubation period, because they need more moisture than hen's eggs. Newly hatched goslings can be brooded rather like

EMBDEN GOOSE.

ducklings, and can be taken off heat at ten days of age. Chick mash, or pellets fed three times daily, provide their best feed, but by three weeks of age they will be eating grain and grass freely. Rather than give them nothing but grass during the summer months, a daily feed of layers pellets is recommended. About one month before killing they can be fed more pellets plus a feed of wet mash containing groundnut oil (4%).

Goose feathers are valuable, about 1 lb. being obtained from each mature goose, and they may fetch up to 10s. per lb. for the finer down. In Holland geese are plucked twice a year—alive—but this practice has not been adopted in this country.

Diseases.—Geese are comparatively disease resistant, and in this country seldom suffer from any epidemics except when they become heavily infested with gizzard worms or coccidia. Goslings require careful management during their first two to three weeks in case of chilling, impactions of the intestines, etc., but from then on they usually make good progress.

#### MORTALITY.

The degree of mortality experienced during the rearing season often gives an indication as to the efficiency of the poultryman and his methods. Providing that there are no actual outbreaks of disease, the following are average figures:—

		Mortality, %.
Chicks	1-8 weeks	5
	9-26 weeks	5
Pullets	6-18 months	10-15
Hens	19-30 months	8-12

#### PREVENTING FEATHER PECKING AND CANNIBALISM.

Apart from attention to management—keeping birds occupied by continuous dry-mash feeding,

pecking at greenfood, roots, etc.—there are three main methods used for controlling these vices.

**Hen Spectacles.**—These are made of plastic or of light-metal alloys and fit snugly over the upper beak so as to cover the eyes in order to interfere with long vision. Thus, a bird fitted with "Dewdrop" spectacles can be expected to see its food but not its neighbours, and therefore Vent Pecking and Cannibalism are prevented.

**De-beaking.**—This operation is carried out for a similar reason, and although the upper beak can be pared with a sharp scalpel or knife, a special cauterising (electric) instrument is preferable. Considerable skill is necessary in de-beaking, because unless an adequate portion of the beak is removed it will quickly grow again, whereas if too much horn is removed the operation becomes painful.

**Visors.**—Visors made of metal, like hen spectacles, are applied to the bridge of the nose, and are now being popularised for use with turkeys. They are kept in position by means of a split-pin passed through the nostrils. Turkey "bits" are equally successful in preventing feather pecking. These consist of a rustless metal ring (incomplete) which lies between the mandibles but above the tongue: its ends are inserted into the nostrils and clipped into position.

#### DISEASES OF POULTRY.

It should be remembered that, in the case of some diseases, birds which recover remain as carriers of the causal germs; this applies particularly to B.W.D., Infectious Colds, and certain Salmonella infections. For this reason alone it is wise to purchase all one's stock from one source and not go to two or three suppliers, or there will be two or three chances of introducing infection on to one's premises.

When any birds die they should either be incinerated or buried deeply in lime, but in the case of commercial poultry farmers it is a good plan to have such birds examined *post-mortem* by a veterinary surgeon or some other competent person, who will be able to state from what the bird has died and what steps to take in order to prevent other poultry from catching the same complaint.

**Quarantine.**—Whenever birds are purchased or brought back from Laying Trials, Shows, etc., it is a good plan to keep them isolated in quarantine for three or four weeks, during which time if they are going to suffer from any infectious disease it should show itself.

**Disinfection.**—Before attempting to rear chicks always make certain that the brooder house and equipment are thoroughly disinfected. Food and water troughs, hovers, etc., should be scraped and soaked in hot, strong, soda water ( $\frac{1}{2}$  lb. to a gallon); immersed in a disinfectant (Jeyes Fluid 1:100), and finally rinsed in clean, cold water. In this way disease germs and viruses will be destroyed and the equipment rendered quite suitable for future use. In the case of incubators, all removable parts should be similarly treated, the remainder of the machine being fumigated with formaldehyde gas (3 oz. formalin added to 1½ oz. potassium permanganate per 100 cu. ft.).

Feedstuffs are normally quite free from infection, but water supplies are occasionally contaminated. This can be dangerous, and efforts should be made to prevent poultry from drinking from puddles or other infected sources. Spring water, running streams, and tap water are, of course, normally quite safe to use.

#### COMMON POULTRY AILMENTS.

**Aspergillosis**, due to a fungus, causes respiratory symptoms in all species of poultry with gasping as the most prominent symptom; mortality is high. The lungs and air sacs show multiple pale nodules. There is no treatment. Avoid musty hay in chick-boxes; mouldy straw bedding, etc. Sterilise feed and water containers daily. This disease can be transmitted to man.

**B.W.D. (Pullorum Disease)**, due to a specific germ, attacks chicks and poulters during the first few days after hatching, and mortality is high. White diarrhoea may be evident. The new drug *Furazolidone* ("Neflin") is believed to be very valuable for treating B.W.D. in chicks and even

for eliminating a high percentage of "carriers." B.W.D. is egg transmitted, and all breeding stock should be blood tested each season before use. When hens die from this disease they show degenerate, nodular ovaries from which can be cultivated the causal germ *S. Pullorum*.

**Big Liver Disease (Lymphomatosis)** is a form of Fowl Paralysis, the liver appearing four to five times as large as normal; all other organs may appear normal. Affected pullets often show a scanty, green diarrhoea a short time before death. Believed to be caused by a virus, there is no cure or treatment for Big Liver Disease.

**Bumblefoot** represents a local infection of the ball of the foot. Usually only one foot is involved, and the site of entrance of the pus-forming bacteria is seen easily. Occasionally the trouble is tuberculous, but more frequently it is due to cocci which penetrate to the region of the tendons below the foot, where the pus which they form shows as a marked swelling. Surgical treatment is often successful.

**Cloacitis (Vent Gleet)** is an inflammation of the vent, commonly seen in pullets; its origin is not clear, but it is certainly not the venereal disease believed in by many farmers. Some cases respond to local treatment, but in many others a stench develops which indicates clearly the unsuccessful nature of the treatment, and such cases are better killed.

**Coccidiosis** is a specific disease of the intestines affecting chickens, turkeys, and occasionally geese, but ducks are immune. There are two main forms: (i) caecal, and (ii) intestinal. Both are caused by microscopic parasites—coccidia—whose life cycle is completed in the mucous membrane lining the gut. Affected birds appear listless, ruffled in the feathers, and many die. Acute Caecal Coccidiosis is characterised by bloody droppings; in the intestinal form diarrhoea may be prominent. In geese the kidneys are frequently attacked. Treatment using sulpha drugs is highly effective. Sulphamezathine (I.C.I.), Avisol, and Embazin (M. & B.) are all satisfactory and can be given in the feed or water. Nitrofurazone is also effective against Caecal Coccidiosis. Each coccidium gives rise to its own immunity, so that a chick having suffered from Caecal Coccidiosis will not again suffer, but it may be attacked later by one of the other intestinal forms of Coccidiosis. The sulpha drugs mentioned cure the disease and also allow immunity to be developed at the same time. For *duodenal coccidiosis* the new drug nitrophenide is good; for chronic cases the feed should also contain an antibiotic at high level.

Colds may either affect isolated birds or be of a highly infectious nature. Sneezing, coughing, gasping, and a swelling of the face and wattles appear in this disease, which is commonest in growing stock. Sulphathiazole (M. & B. 760) and allied drugs are specific for certain types of infectious colds, and should be given at the earliest opportunity. Pullets at point-of-lay will quickly go out of production for some weeks, but they may lay just as well at a later date. Mortality is not usually high, but stunting occurs in many cases, and severe culling is necessary. Infectious colds are considered by many farmers to be their worst enemy after Coccidiosis and Fowl Paralysis.

**Crooked Breastbones** occur in young stock receiving improper feeds lacking calcium, vitamin D, etc. Some strains and breeds are more susceptible than others. In laying stock too little grit may have been fed.

**Crop Binding** is a stoppage of the crop, generally through eating long grass, straw, etc. It never occurs in hen batteries or on deep litter, but may be seen in hen yards, and it is commonest in birds kept on free range. Good management will avoid most cases, the remainder require surgical treatment.

**Diphtheria** (see Fowl Pox).

**Dropsy** is characterised by an accumulation of fluid in the abdomen. It is often secondary to cancer of the intestines. There is no cure or prevention, and affected stock should be killed and buried.

**Egg Binding** implies an impaction of the oviduct either by yolks or shell-less eggs, etc., or it may refer to cases where a fully shelled egg has failed to be extruded at laying time. The former cases are without treatment, but the latter can be re-

moved by manipulation. Only isolated cases occur, and their prevention is not easy.

**Fowl Cholera** is a specific disease due to a germ—*P. avicida*—affecting all species of poultry and having a high death-rate. Sometimes there is a swelling of the wattles with local abscess formation. Affected stock suddenly become ill, the birds are dejected, and a number will die overnight. Sulphaquinoxaline and sulphamerazine may be used to reduce the death-rate.

**Fowl Paralysis**.—The Fowl Paralysis "complex" comprises cases of leg, wing, neck, and eye paralysis, all due to an infiltration of the parts by an accumulation of abnormal cells. A second form of the disease, characterised by tumour formation, is known as Lymphomatosis, and included in this group is "Big Liver Disease." These diseases are all believed to be due to viruses, but there is no cure or any medicinal treatment of value. Many of them are of an infectious nature, spreading amongst young stock during the first few weeks after hatching, but a few cases may be egg transmitted.

The domestic fowl is chiefly affected, frequently pullets at point-of-lay; turkeys are but rarely involved, whilst ducks and geese never suffer from Fowl Paralysis. Some families and breeds are more resistant or susceptible than others, and pedigree breeders are now trying to establish Fowl Paralysis resistant strains. To minimise the introduction of these diseases, purchase all replacement stock from one source only at day-old. Rear them as far apart as possible from all other poultry, especially adult layers. Keep them so isolated for as long as practical, certainly 8-10 weeks.

**Fowl Pox** is due to a virus, and is characterised by wart-like or cheesy growths on the comb, eyelid, face, and wattles. Chicken, turkeys, pigeons, and canaries can all suffer from pox; ducks and geese appear immune. When the mouth or throat are involved the disease is termed *Avian Diphtheria*.

Treatment is not very satisfactory, but iodine applications daily are worthwhile. Prevention is by the use of vaccines—*Pigeon Pox Vaccine* giving a shorter period of immunity than that following the use of *Fowl Pox Vaccine*. Such vaccines only cost 1d.-2d. per doze, and as immunity is established in fourteen days, their use is well worthwhile.

**Fowl Typhoid** is caused by a germ—*S. gallinarum* (closely allied to that of B.W.D.)—and gives rise to symptoms and losses easily to be confused with those of Fowl Cholera, hence the need for expert advice. Dramatic results have recently been achieved using "Neflin" experimentally as a treatment for typhoid.

**Gapes** is a disease of young chicks aged less than eight weeks, and also of turkeys. Rooks and many other wild birds harbour gapeworms which live in the wind-pipe, where they cause irritation, gasping, and suffocation. Barium antimonyl tartrate is the best treatment used as an inhalant (powder).

**Infectious Laryngo Tracheitis (I.L.T.)** is a specific, highly infectious, fatal disease affecting fowls. The causal virus first induces "colds," gasping, and the coughing up of blood; but numerous deaths follow. Recovered birds are often carriers. There is no treatment.

**Leg Weakness** is a symptom and not a disease. It may be seen in Rickets (chicks); Fowl Paralysis; Layer's Cramp (hens); worms and Coccidiosis; dietetic errors, etc.

**Lice** (see Parasites).

**Liver Disease** is a term used to indicate those diseases characterised by a gross deformity of the liver, e.g., Tuberculosis (nodules of the liver); internal hæmorrhage from rupture; fatty degeneration of the liver—as in phosphorus poisoning; Leukæmia, Big Liver Disease, etc.

**Marble Bone Disease** affects cockerels, revealing enlarged thickened bones, especially in the legs and wings. It is incurable, and there is probably a genetic aspect to the problem, and known parent stock should not be used again for breeding purposes.

**Newcastle Disease (Fowl Pest)** is a notifiable disease causing serious losses to the industry, with respiratory and nervous symptoms, nasal discharges, diarrhoea, gasping, twitching, paralysis, and death. One form in adult birds shows only as an infectious type of mild cold (without serious

losses)—egg production falls dramatically. It is an airborne infection of virus origin for which there is no cure, nor is any preventive vaccine available in this country as yet.

Parasites are divided into: (i) external and (ii) internal. The former comprise lice and mites (common) and fleas (uncommon). Some harm may be caused by their irritation. They can be eliminated by the use of D.D.T., Gammexane, nicotine sulphate perch paint, etc.

Internal parasites consist of coccidia (see Coccidiosis) and worms. The latter are common in stock housed on old pastures, but rarely seen in hen batteries. The Large Round Worm (*Ascaridia*) may do harm, but the common caecal worm ( $\frac{1}{2}$  in. long) rarely causes any trouble; hairworms in the crop, gizzard, and small intestines are also important. Tapeworms require the presence of an intermediate host (slug, snail, etc.), and may be a serious cause of loss. Flukes are rare in waterfowl, but *Acuaria* are more common.

Peritonitis refers to an inflammation of the membrane (peritoneum) which lines the abdominal cavity. The commonest form affects laying stock and follows an infection (ascending) of the oviduct. It is seen, too, in certain cases of blood poisoning and also following perforation of the gizzard or intestines. It is usually fatal and not detected before death.

Pneumonia is common as a terminal feature to congestion of the lungs following chilling. It is seen also in Aspergillosis in chicks (Brooder Pneumonia) and B.W.D.; antibiotics (e.g., penicillin) or sulpha drugs can be used for valuable poultry suffering from pneumonia.

Prolapse of the intestines or oviduct results from an eversion of the cloaca and associated parts. The cause varies, but may be of digestive or reproductive origin. Some cases can be corrected if caught early, the parts being anointed and replaced; preferably being held in position for twenty-four hours by a suture. Feed sparingly for two to three days.

Tuberculosis is a specific disease of germ origin, fortunately rapidly becoming eliminated nowadays by the adoption of modern housing practices. It is never seen in young stock, but chiefly affects hens, which lose condition and die. Post-mortem findings are typical, revealing nodules in the liver, spleen, intestines, lungs, bone marrow, etc. There is no curative treatment, but many infected birds can be detected by a blood test (Tuberculin Test).

Tumours are growths of a cancerous nature. They are commonly found in pullets, involving the ovary, lungs, liver, intestines, and kidneys. Some are due to a virus; many show a familial tendency. Very few are capable of being treated, but *Blood Blisters* may respond to cautery, using a caustic pencil or a piece of bluestone rubbed well into the cyst.

Vitamin and Mineral Deficiencies are less common to-day, due to the use of specially compounded poultry feeds which include synthetic vitamins A, B<sub>2</sub>, D<sub>3</sub>, cod-liver oil, dried yeast, etc. Cases of Rickets, Curled Toe Paralysis, Dermatitis, and Nutritional Roup are, therefore, becoming rare, and "Slipped hock disease"—of manganese deficiency origin—is often recognised early and treated successfully. The ratio between the calcium and phosphorus contents of the diet are important, otherwise leg and bone weaknesses may result.

### CULLING POULTRY.

The object of "culling" poultry is to find those which are not paying their way—the duds, the "passengers"—those birds eating a full ration but giving nothing in return.

Culling should be a continuous process, right from hatching time, for there is obviously no sense in keeping even day-old chicks if they are soon going to be unproductive.

Culling can be considered as both an art and a science, and can be applied for either (a) general health, or (b) egg production.

### Handling Poultry.

Before any accurate examination of birds is possible it is necessary to know how to handle them—how to pick them up so that they remain quiet, as well as the method by which each part is examined in turn. If the poultryman's hand is

placed below the bird's breast (with its head turned towards the operator) with the fingers separated so that the little finger and thumb are controlling the bird's two hooks this will be found useful. The other hand is then free to raise the bird's head, to palpate the abdomen or move the feet, etc.

### Health and Disease.

The following culling points are important:—

Comb covered by scabs occurs in Fowl Pox.

Eyes lose their colour in Iritis and blindness.

The pupil may be "split" or even paralysed.

Face is covered by whitish, powdery scales in Favus.

Nostrils show thick mucus in "Colds."

Mouth contains yellow growths in canker ("Diphtheria").

Wattles swell due to the presence of pus, and also in some cases of Fowl Cholera and Coryza.

Wings should be examined for loss of feathers in moulting.

Skin shows the presence of blood blisters, wounds, etc.

Breast may be crooked, or affected by a blister (cyst).

Vent reveals cases of prolapse, and in Vent Gleet it has a nasty smelling discharge. The vent fluff reveals the presence of lice or their eggs and mites, also diarrhoea and nephritis.

Shanks indicate age, and also the presence of Scaly Leg.

Toes may be crooked, twisted or curled.

Toe Nails are short in birds from range (due to scratching) and long in birds from hen batteries.

Foot may be swollen due to Bumblefoot.

Back may reveal impaction of the preen gland at the root of the tail.

Abdomen may be hard due to tumours, to impacted egg material, liver enlargements, or sometimes full of fluid (dropsy), etc.

### Egg Production.

Pullets in production usually show combinations of the following points:—

Head.—Comb large and full blooded, silky. Wattles close set—if widely separated this indicates the beefy type, and is due to fat beneath the skin. The eye is set high up in the skull, is prominent and visible from both the front and back of the head. The eyebrow is not overhanging, and the eye fills the socket. The neck is swan-like.

Abdomen shows four fingers' width between the point of the breastbone and the pelvic bones.

Pelvic bones are separated by three fingers' width.

In the case of birds out-of-lay the pelvic bones contract, and the breastbone more nearly approaches the vent.

### PIGEONS.

Large numbers of pigeons are kept in this country as a hobby, and only a few are reared as table birds. Pigeon racing is a popular sport, but during war or emergency periods they are also used for message carrying, postal services, etc.

Although pigeons belong to the Order *Galliformes*, they are in a different sub-order from that of poultry, and *Columba livia*, the Asiatic Grey Rock Dove, is believed to be one of their main ancestors.

In all there are upwards of 200 breeds of pigeons, but of these the Fantails, Tumblers, and Pouters always attract most attention. The larger breeds for table purposes are Mondains, Runts, Dragons, and various crossbreeds.

Foods and Feeding.—A pigeon's diet should be mixed and consist of seeds, grains, greenfood, and grit. The chief foods used are: peas, especially Tasmanian maple peas; Tick beans; tares (vetches); millet; canary seed; lentils; linseed; and corn of all varieties. When no greenfood or maize is available, and during the winter months particularly, vitamins A and D should be supplied in synthetic form or alternatively as cod-liver oil. Short-beaked breeds are best given small or cracked peas, tares, canary seed, etc. Regular supplies of gravel, granite, or flint grit are necessary, as well as limestone grit, especially during the egg-laying season.

It is fallacious to supply pigeons with flowers of sulphur in the belief that this provides sulphur

for the growth of feathers; nor is it necessary to give beans for supplying silica or oyster-shell for iodine. Charcoal is another unnecessary ingredient for pigeons.

The average pigeon eats about 1½-2 oz. of grain daily, the lesser quantity being given to racing pigeons, but during the brooding season a much larger appetite is to be expected when pigeon "milk" is being formed in the crop.

**Breeding and Rearing.**—Pigeons will breed in any month of the year, but mating naturally takes place in late February or March, and continues to August or September. A second clutch of eggs is often laid before the first brood is fully fledged. The average hen lays seven to eight days after mating—never earlier than the fifth day. Gliding is often a sign of courtship. The hen may sit on the nest three to four days before laying her first egg in the afternoon; the second egg follows about thirty-six hours later. The hen usually sits on them during the night-time, whilst the cock incubates them during the day. The incubation period is seventeen to eighteen days. For normal purposes pigeons can rear half a dozen broods each year, but in order to conserve their energy only one or two should be taken from racing pigeons; it is then also recommended that only one squab per brood is reared. Squabs usually hatch in the morning, never after 3 p.m.

The parent birds brood their young for a full week after hatching, thereafter they may be left uncovered without harm. It is during this first week that identification rings must be put on to the legs of young pigeons. By the end of the second week the young birds will leave their nest; during the whole of this time they live on food regurgitated from the parent's crop. This food is called "Pigeon's Milk"; it is the direct result of a hormone (produced by the brain), and is caused by an overgrowth of the lining membrane of the crop which sheds itself as "milk." It is a highly digestible, whitish, semi-solid, granular product passed direct (from either parent) to the mouth of the young squab. It is not a glandular secretion, and to the naked eye looks rather like soaked groats. Early during the brooding period the parent birds "vomit" part-digested grain to their offspring as well as "milk." Foster mothers may be required for Croppers, Pouters, and Short Faced Tumblers, etc. Weaning takes place after three to four weeks, in fact, as soon as the squabs can feed themselves and become independent of their parents. The growth rate and physical development of the young pigeon is quite dramatic from day-old onwards. It is then only covered by brightish yellow, hair-like down, and its skin is devoid of pigment matter. It is extremely weak at this stage, and its eyelids may remain closed for four to five days. By the end of the first week, however, its pigmented quills give it a porcupine-like appearance, and by fifteen days of age the whole bird is covered with feathers. For all practical purposes pigeons are mature by twenty-six days of age, being alert, fully feathered, and typical of the species.

An area devoid of feathers circumscribing the eyelids is known as the "cere"; some breeders pay great attention to this character, but it is really unimportant physiologically. The breast muscles are strongly developed and of deep red colour in contrast with those of poultry. The lining, horny membrane of the gizzard is often coloured green, due to bile; it should always contain insoluble grit for grinding the food. No gall bladder is present, and the caecal tubes are diminutive. The small intestines are coiled in a spiral fashion. During the mating season the ovary will show only two well-developed egg yolks which, with the large oviduct, occupies almost half the abdominal cavity. Compared with other birds, the heart and lungs are large, especially in racing pigeons. The body temperature registers 107° F. Moulting usually begins in April or May, and it is at this time that the primary flight feathers are lost.

**Aviaries and Lofts.**—It is usual to build a special pigeon cote for their sleeping, feeding and breeding activities. Such lofts should be white-washed twice a year, and if D.D.T. is added it will help to control flies. A wire-mesh aviary attached to the loft for exercising purposes is

common, a minimum of 3 sq. ft. of floor space per bird is recommended, and for fifty pigeons 15 ft. x 12 ft. is satisfactory. For the loft floors sand or sawdust make good litter, but it should be raked over and sifted frequently to remove the bulk of the droppings. Most lofts, nest-boxes, and perches are made of wood, and where space is restricted the nest-boxes can be attached to an outside wall with their entrance direct into the loft. A nesting-box of two compartments separated by a low partition allows the cock bird to take charge of the first brood whilst the hen sits on the second lot of eggs. Nest-boxes should be 14 in. x 14 in. x 28 in. If the front of the nest-box is protected by a 3-in. wooden board, hinged at the bottom, this will help to confine the squabs. An alighting board 4 in. wide in front of each nest is valuable.

**Racing and Training.**—Young pigeons are generally flying quite satisfactorily by their seventh week, and they should soon be given two exercise flights daily until able to fly for three-quarters of an hour. Before training begins, such young birds must be made to get used to their baskets, followed by "trapping" and learning to recognise their owner's particular call. Consistent light training is better than intensive methods, and should begin when the birds are about four months old, and flights should be extended gradually from three miles to 100 miles as progress is made. Quick trapping to avoid loss of time after races is gained by feeding only inside the loft and by calling the birds through the trap by a whistle or other standard noise. Feeding should always be carried out after exercising.

**Homing.**—Many birds, other than pigeons, have homing instincts, and these are not confined to the brooding season. Homing is an inherited quality of uncertain origin which can be developed by selective methods and directional training. It is now generally considered that the primary sense of orientation is not related to visual landmarks, but navigation as such may be related to the position of the sun. Homing is not affected by radar, and although it has been suggested as due to magnetic influences, the use of Faradic cages has disproved this point.

Homing pigeons may fly at heights up to 6,000 ft., but in poor visibility they will come down to within a few feet of the ground. In thick fog they soon appear to lose their sense of direction and descend until the weather improves, but large numbers of birds are lost annually from this and associated causes.

The method of handling a pigeon is important. It should be held in one hand with the thumb across the back, the fingers and the palm of the hand below the abdomen with the first and second fingers lightly gripping the feet.

**Diseases of Pigeons.**—Diseases of the digestive system account for more losses than any other. A thread worm, *Capillaria*, is a common cause of enteritis with marked loss of condition; but *Coccidiosis* also attacks the small intestines. "Sulpha" drugs are now available for the treatment of this disease. *Trichomoniasis* is another common disease of pigeons, it affects the liver and upper part of the digestive tract. *Salmonella* infections account for a very large number of deaths, especially in young pigeons, one form of the disease being termed "Paratyphoid." Arthritis sometimes occurs in pigeons, and it too may be associated with *Salmonella* infections.

Many young birds suffer from *Coryza* (cold), and fanciers often associate the chronic form of this disease (Roup) with Pox. Pigeon Pox affects mainly the head and eyes, but unlike poultry, many cases do not respond to treatment with tincture of iodine or copper sulphate (1 per cent.). Sudden death (Apoplexy) is sometimes seen in pigeons, but the cause is seldom determined: internal hæmorrhage is associated with many cases. Pigeons can be affected by an important virus disease called *Psittacosis*. Although some cases are transmissible to man, fortunately very few pigeon fanciers suffer from this disease, which is characterised by fever, malaise, and an unusual form of pneumonia. *Aspergillosis* may also be contracted by man from infected pigeons.

Lice and feather mites are common external parasites of pigeons, but their control is easy, due to the use of specific remedies, e.g., D.D.T.

# Domestic Pets

By ALASTAIR N. WORDEN, M.A., B.Sc., M.R.C.V.S., F.R.I.C., formerly Milford Professor and Director of Research in Animal Health, Univ. College of Wales, Aberystwyth.

This section attempts to deal not with all the many hundreds of animals that may be kept as pets, but only with those that are best suited to average homes in Great Britain. The maintenance of monkeys, squirrels, bats, mongooses, and snakes, while quite feasible to those with experience and facilities, requires considerable time and—in some instances—expense. Those who contemplate such exotic pets should consult works of reference, study the methods adopted in zoological gardens, and discuss the matter with experts. Even in the case of the more common animals, the information provided in the following pages is to be regarded only as a beginning, to be supplemented as far as possible by practical experience, discussions with more knowledgeable owners, and the study of more detailed writings.

Certain considerations are basic. Never keep a pet unless you are really interested in it and are prepared to give it due—and regular—care and attention. Don't keep a pet you cannot afford to maintain in health and comfort. Scrupulous attention to cleanliness is essential, and wise feeding is one of the most important factors in avoiding illness and loss of condition.

Since the passing of the Veterinary Surgeons Act of 1948 it is illegal for anyone to practise the diagnosis and treatment of animal diseases unless he or she is: (1) a veterinary surgeon; or (2) a person whose name has been placed on the Supplementary Veterinary Register. (Certain employees of Animal Welfare Societies are specially licensed, but it is intended that in future all animal treatment shall be given by or under the direct supervision of members of the veterinary profession.) Not even a pharmacist may attempt to diagnose or treat an animal. Anyone may, of course, render "first aid," and an owner may—at his or her own risk—apply treatment. It is, of course, a wise precaution to seek veterinary advice for any ailing animal, and the sooner it is sought the more likely it is that good results will follow.

## BREEDS AND VARIETIES OF DOGS.

Of recent years, dog-breeding and showing have become specialised occupations, which average people cannot be expected to take up without having adequate time or resources at their disposal. Any amateur who wishes to breed for profit from pedigree animals should most certainly seek expert advice before attempting to do so.

Dogs which are intended for show or for pedigree breeding must be registered with the Kennel Club, 84 Piccadilly, London, W.1. The requisite forms and regulations may be obtained on application to the Secretary.

The breeds of dogs recognised for the purpose of separate Registration and Stud Book entries by the Kennel Club are:—

### SPORTING BREEDS.

Afghan Hounds	Finnish Spitz
Basenjis	Foxhounds
Basset Hounds	Grayhounds
Beagles	Harriers
Bloodhounds	Irish Wolfhounds
Borzoi	Otterhounds
Dachshunds	Salukis
Deerhounds	Whippets
Elkhounds	

### Gun-dogs.

English Setters	Retrievers
Gordon Setters	Setters (Cross-bred)
Irish Setters	Spaniels
Pointers	

### Terriers.

Airedale Terriers	Lakeland Terriers
Australian Terriers	Manchester Terriers
Bedlington Terriers	Norwich Terriers
Border Terriers	Scottish Terriers
Bull Terriers	Sealyham Terriers
Cairn Terriers	Skye Terriers
Dandie Dinmont Terriers	Staffordshire Bull Terriers
Fox Terriers	Welsh Terriers
Irish Terriers	West Highland White Terriers
Kerry Blue Terriers	

### NON-SPORTING BREEDS.

Alsatisans (German Shepherd Dogs)	Chow Chows
Boston Terriers	Collies
Boxers	Dalmatians
Bulldogs	Dobermann Pinschers
Bull-mastiffs	French Bulldogs
	Great Danes

Keeshonds	Schipperkes
Mastiffs	Schnauzers
Newfoundlands	Miniature Schnauzers
Old English Sheepdogs	Shetland Sheepdogs
Poodles	Shih Tzus
Pyrenean Mountain Dogs	Tibetan Terriers
St. Bernards	Welsh Corgis (Cardigan)
Samoyeds	Welsh Corgis (Pembroke)

### Toys.

Black-and-Tan Terriers (Miniature)	Maltese
Griffons Bruxellois	Papillons
Italian Greyhounds	Pekingese
Japanese	Pomeranians
King Charles Spaniels	Pugs
	Yorkshire Terriers

A separate register, called the Breed Register, is kept by the Kennel Club for each breed, except in the cases of the following breeds, for which a separate register is kept for each of the varieties of the breed specified.

### DACHSHUNDS.

Long-haired	
Smooth-haired	
Wire-haired	
Miniature (Smooth-haired) (not exceeding 11 lb. for exhibition.)	
Miniature (Long-haired) (not exceeding 11 lb. for exhibition.)	

### IRISH SETTERS.

Red	
White and Red (A.O.V.)	

### RETRIEVERS.

Curly-coated	
Flat-coated	
Golden	
Labrador	
Interbred	
Crossbred	

### COLLIES.

Rough	
Smooth	

### SPANIELS.

Clumber	
Cocker	
Field	
Irish Water	
Springer, English	
Springer, Welsh	
Sussex	
Interbred	
Crossbred	

### BULL TERRIERS.

Bull Terriers	
Bull Terriers (Miniature).	

### FOX TERRIERS.

Smooth	
Wire	

### POODLES.

Not under 15 in.	
Miniature, under 15 in.	

### TOY SPANIELS.

Cavalier King Charles Spaniels.	
King Charles Spaniels	

The Committee of the Kennel Club has decided to classify those breeds which at present have no separate register, but are included under the

heading "Any Other Variety." The classification is as follows:—

HOUNDS.	NON-SPORTING.
Dachsbracke	Bearded Collies
Dachshund Miniature (Wire-haired)	Bouvier de Flandres
Rhodesian Ridgeback	Groenendael
Lion Dog	Hudky
	Leonberger
	Lhasa Apso
GUN-DOGS.	Maremma Italian Sheep-dog.
Chesapeake Bay Retriever	Norwegian Buhund
Kleine Munsterlander	Polish Sheepdog
Pointer German Short-haired	Reisenschнауzer
Pointer German Long-haired.	Tibetan Mastiff
Pointer German Wire-haired	Tibetan Spaniel
Pointing Griffon Wire-haired	Volpino
Setter German Long-haired	Wolf Spitz
Weimaraner	

#### TERRIERS.

Soft-coated Wheaten Terrier  
Sydney Silkie

#### TOYS.

Chihuahua  
Penscher Miniature

In the limited space available it is impossible to describe the special characteristics of the different breeds. The breeds recognised in Great Britain are subject to constant review by the Kennel Club, and it is probable that the number will continue to be added to from time to time.

The dog was probably the first animal to be domesticated in the true sense of the word, and the uses to which he has been put by man are almost legion. Throughout the world dogs are employed to help protect herds and flocks, and indeed the dog trained for herding plays an integral part in sheep management. The names Foxhound, Deerhound, and Otterhound all indicate the specific uses to which dogs have been put in the Chase. Greyhounds and Whippets are used in coursing, and work singly or in pairs, rather than in packs. As their names indicate, the various Setters and Pointers are employed to indicate the exact whereabouts of game, and Spaniels also are widely used as gun-dogs. The other uses to which dogs have been put in field sports include hunting over rough and difficult country by small terriers, and going to earth to kill or hold badgers, foxes, and otters. Fox Terriers, Dachshunds, Dandie Dinmonts, and Scottish Terriers are among the types which have been so employed. Dogs have played their part also in entertainment: thus there are performing dogs, notably the Poodle, and racing Whippets and Greyhounds, while in former times various types of fighting, including the baiting of bulls by Bull-dogs, were to be seen. The use of sledge-dogs is well known, while in Belgium and elsewhere dogs were at one time widely used as traction animals. In coaching days, the Dalmatian was a carriage dog, and modern scientists have recently suggested, as a result of experiments, that the position under or behind a coach which a Dalmatian automatically takes is determined by heredity! Perhaps the most exacting use to which man has ever put dog was in China, where the Chow-Chow was once maintained as a source of meat and fur! In Portugal, fishermen employ a race of dog to accompany their fleets. The dogs in question (Portuguese Water Dogs) will dive into the sea to retrieve a broken net or an escaped fish, and will even swim from one smack to another to convey messages! In New Guinea native dogs act as scavengers, while in various countries on the Continent of Europe "truffle dogs" are employed to locate the fungi known as truffes, relished as a table delicacy.

The above paragraph is far from exhaustive, and for those who wish to know more of the characteristics of the different varieties of dogs, reference should be made to such volumes as *Book of the Dog* by Brian Vesey-Fitzgerald (2 guineas) or *Working Dogs of the World* by C. L. B. Hubbard (16s.). For general guidance on dog management, see *The Right Way to Keep Dogs* by R. C. G. Hancock (6s.).

For present purposes it is, however, as a pet or companion that we are considering the dog, and it must be agreed that many of the most successful animals for this purpose are cross-breeds or "mongrels." There are many fallacies or unsubstantiated generalisations regarding the relative merits of pure-breeds and mongrels. This is in fact an intricate scientific problem, and probably the simplest way of summarising the true position would be to say that, from the point of view of health and temperament, there are good, bad, and indifferent specimens among pure-bred and cross-bred animals. It is true that within a breed (or within a local community of mongrels for that matter) certain weaknesses or undesirable traits may arise from hereditary defects.

It may be noted that the word "dog" is applied to the whole species, although it is used also to denote the male as opposed to the female, for which the correct term is "bitch." Young animals are referred to as "dog puppies" or "bitch puppies" respectively. A male animal employed regularly for breeding is known as a "stud dog," and the corresponding female as a "brood bitch." In hunting circles the Foxhound is referred to as a "hound," and the term dog and bitch are employed only as prefixes to denote the sex.

#### CHOICE OF DOG.

However attractive the idea of keeping a dog may be, it is unwise and unkind to purchase or to accept one without very careful consideration. Dogs require regular feeding, grooming, and exercise and, if they are to be allowed to show their full capabilities, constant companionship and attention. Nothing is more pathetic than the unwanted dog, which may have been purchased because of a passing whim, and with which no one appears to have the courage to part. If, on the other hand, one is prepared to give all the necessary time and trouble to the proper care of the dog, the reward will be ample.

The size of the choice is important. Many people keep dogs which are far too large for their houses and for their purses. The smaller the dog, the less food, exercise, and house-room will be needed, and the many varieties of terrier provide a range from which suitable choices for most households may be made. In any event, a very large dog should not be chosen unless expert advice has been taken about his feeding and other requirements.

Household dogs of six months of age or over must be licensed. Licences may be obtained from any post office.

#### MANAGEMENT OF THE DOG.

**Accommodation.**—Up till comparatively recently, most dogs were kennelled down out of doors, but to-day the majority of pet dogs are allowed more or less the run of the house. A warm sleeping-place, such as a box or basket, should be provided, and should contain removable bedding. Newspaper is an excellent non-conductor of heat. It is a very useful material to place at the bottom of a dog's box; and on two or three thicknesses may be placed a rug or blanket on which the animal may lie. It is astonishing the amount of grit and dust a dog can bring into a house on his limbs and the lower part of his body. His bedding will require frequent shaking out and renewal, and paper is easily changed. The box or basket in which the dog lies should be allowed a place free from draughts, and requires airing daily when the dog leaves its bed in the morning. Wood-wool makes excellent bedding in outhouses or where a special structure is provided by way of dog-kennel, but is inclined to be messy about the house, as a dog will draw portions of it about the room as he leaves his bed. If straw is used, it is best stuffed into a sack and made into a kind of mattress. An odd piece of linoleum forms an excellent foundation to the dog's sleeping-box or kennel; it does not strike cold to the skin, is a slow conductor of heat, and has the advantage of being easily kept clean, particularly during illness, when there may be discharges and messes to be frequently cleaned up, until the animal can once more go out of doors.

**Exercise.**—Every dog should be exercised regularly, but there is no need to over-exercise, and the practice of allowing a dog (other than a large and athletic animal) to run behind a bicycle for mile after mile cannot be too strongly deprecated. Two or three fairly short walks a day are sufficient for a small terrier, always providing there is a garden in which he can play on fine days and some open space where he can run freely for a short time. While still in the puppyhood stages, a dog should be trained to walk to heel and to beware of traffic. Even so, it is usually safer to put him on a lead in busy thoroughfares. One point which, to the annoyance of the public, many dog-owners fail to realise, is that their animals would show much less tendency to fight if allowed to investigate one another off the lead. A dog naturally feels aggressive if put on the lead immediately a rival hails in sight. There are, of course, certain dogs which attack others at sight; these are a public nuisance, and should never be allowed loose on the streets.

The practice of allowing a dog to take his own exercise is to be deprecated, especially in towns and suburbs. The animal will be tempted to sniff into dustbins, and, if a male, will tend to follow a bitch in season or to take part in the unsavoury "dog parties" which are so often to be seen. Furthermore, such an animal is usually responsible for the disgusting habit of fouling the pavements and gateways. In this connection, it should be emphasised that dogs may quite easily be trained to defæcate in the gutter, or on the grass verge, and so avoid contamination of the pavement or carriage-way. In some districts owners are liable to a fine if their dogs foul the pavement.

**Training.**—Patience combined with the gift of putting yourself in the dog's place is the chief requisite for successful education. It is most important to encourage regularity of habit, as an animal will obviously learn very much more quickly if his daily walks, meals, and grooming take place at fairly constant times. A quiet firmness is the ideal method, and a puppy should learn early that a command is a command, and must be obeyed. There is no need to shout and make an exhibition of oneself, or to race in circles after a disobedient puppy; if these things are done, the animal will never become so well trained as it otherwise would. Again, it is rather ridiculous to chastise a puppy *after* he has somewhat belatedly decided to come to heel: quite obviously, he will then be liable to think that he has done wrong in actually coming to heel. Whatever happens, it must never be that the dog becomes master; there is no more unbecoming sight than that of a person with a frankly disobedient dog, and if the animal be large and powerful it may prove a menace to its owner and to the public.

Puppies should be house-trained at an early stage. If care and thought are given to the matter, the animal will soon learn not to make messes in the house. However, it is very stupid to forget all about a puppy or dog for many hours, and then, out of sheer vexation, chastise it for having made a mess. If puppies are let out every two hours or so at first, they will soon learn not to make a mess. Encourage them for performing in the right place rather than scold them for doing so in the wrong one.

**Grooming and Washing.**—Whilst short-haired breeds need little or no attention to the coat, bar an occasional brisk rub down with a brush or rough towel (which incidentally puts a pleasant gloss on the smooth-haired breeds), yet with the long-haired breeds grooming should be carried out regularly, and if the habit is made a daily one it will not be forgotten so readily. Nearly all dogs love this procedure, and most dogs will actually ask for their daily groom by jumping on the table or bench on which it is carried out. Steel combs and brushes are sold by many shops, principally corn chandlers, though some store chemists also provide a suitable range of grooming kit for all breeds. There is a curious fetish current among many breeders that dogs should not be washed. There is no reason why, with a few simple precautions, a dog should not be washed whenever it is socially necessary. The first precaution is to use a soap that does not contain an excess of soda. The strong washing-up soaps, excellent as they are for certain purposes, are too irritant for a dog's skin. While some

of the toilet soaps suitable for human use may be employed for dogs, the special dog soaps and shampoos are much better for the purpose. They are more suited to the dog's skin and coat, and have better detergent properties. It is important not to have water that is too hot—as with a baby's bath, it should be possible to dip the point of one's elbow into the water and find that it gives a pleasantly warm sensation but is easily bearable, *i.e.*, it should not be above 95–100° F. On emerging from a bath a dog will shake himself thoroughly, and then, if not curbed, will roll on the floor or ground and speedily cover himself with dust or dirt! It is therefore necessary to give him a brisk rub down with old (but clean) towelling, whereupon he may be allowed to dry off in a warm place free from draughts or, in good weather, put on a lead and taken for a brisk walk. In the case of many of the long-coated breeds it is customary to have them trimmed at the beginning of summer, and this is a sensible precaution that may avoid a good deal of distress during hot weather. The smaller long-haired dogs, in particular, such as Scottish Terriers, suffer unduly from the heat if their coats are grown too long.

### FEEDING OF THE DOG.

Meat, usually beef, is generally regarded as the staple article of the dog's diet. It must be pointed out, however, that although the dog is naturally a carnivore (flesh-eater), ordinary meat (muscle or "flesh") is not a completely adequate diet, and lacks certain factors which the wild dog would find in the blood, bones, liver, and other organs of his prey. Furthermore, it has been proved scientifically that dogs can thrive on a meatless diet. In spite of these reservations, however, meat must be regarded as an excellent article of food, and if properly supplemented will prove very satisfactory. In recommendations which have recently been made in America (Dr. S. R. Speelman, of the U.S. Department of Agriculture), it is suggested that meat (beef, lamb, mutton, or horseflesh, providing that the last is fed regularly and not spasmodically) or meat substitutes (fish, milk, eggs, etc.) should constitute one-half of the daily ration, and that the remainder should comprise approximately equal parts of cereal substances (bread, biscuits) and of vegetables (carrots, spinach, onion, beet, etc.). It is pointed out that many dogs do not accept the vegetable material readily. On this basis, the approximate quantities of food required by adult dogs have been calculated as follows:—

Weight of dog.	Total food per day.
1 lb.	2 oz.
10 lb.	12 oz.
25 lb.	1½ lb.
50 lb.	2 lb.
75 lb.	3½ lb.
100 lb.	4½ lb.
150 lb.	5½ lb.
225 lb.	7 lb.

(Weights of up to 10 lb. would include the toy breeds, 25 lb. would correspond to a Fox Terrier; Airedale Terriers and Retrievers would fall into the 50–75-lb. class, and the larger weights would be those of the very big breeds, such as the St. Bernard.) The quantities given are, of course, an approximation and no more. Dogs which lead a very active life will require more, while those which take little exercise, or which tend to put on fat easily, will require less. Common sense is necessary, and great care must be taken not to over-feed or to under-nourish.

Meat is probably best fed raw, or lightly cooked, but many animals appear to have a preference (probably through habit) for well-cooked meat. In any event, the meat should not be "over-done," as there is substantial evidence that prolonged heating destroys much of the food value of the meat protein. Fish is an excellent substitute. There need be no anxiety about the greed with which a dog swallows lumps of meat and also neglects to masticate them. The teeth of the dog are for tearing meat, he is not concerned with biting his food up small; indeed, his salivary glands contain no digestive ferments, as is the case with some other animals.

Milk is almost essential during pregnancy and lactation (see below), and may well be included

in normal dietaries. Whether or not bones should be fed is a matter which has been hotly debated, but for mature household dogs the evidence suggests that they are unnecessary. (The teeth of racing greyhounds, which receive a "sloppy" diet, are quite as good as those of the average household dog.) Bone-feeding is responsible for much trouble, including constipation, actual impaction of the rectum, and lodgement of pieces of bone in the mouth or throat. The value of bones is, of course, that they contain large quantities of essential mineral substances, and for this reason the inclusion in the diet of bone-meal, or of steamed *bone-flour*, or, preferably, a mineral supplement, is recommended. Only very small quantities of these substances are required.

Bread is an article of food which is often overlooked in the case of the dog, but there is no doubt that wholemeal bread is very suitable indeed, provided it is not fed to excess.

The answer to the question whether a dog requires vegetables is, in the main, no. From the Vitamin C standpoint they are quite unnecessary, since it has been shown that a dog manufactures this vitamin for itself, but the fact remains that many dogs, particularly of the toy variety, enjoy a few slices of banana or apple, and there is no harm in letting them pander to their taste.

Clean fresh water must be provided at all times.

In addition to the diets recommended above, there are on the market several tinned dog foods which claim to be complete, or almost complete, diets for the dog. It must be said that many dogs (including those of the writer) have remained in excellent health when receiving one of these foods as a large part of the diet over long periods. There is, therefore, little that may be said against the widespread use of the better varieties of such products. Again, it is a matter for common sense; if an owner finds that his animal is thriving on such a diet, he is wise to continue to use it.

It is customary to give dogs two meals a day. There is no need to give more than two to healthy adults, for the dog's stomach is exceedingly capacious and adapted to long gaps between meals. Many dogs thrive on only one meal in twenty-four hours. Whatever plan is decided on, regularity should be adhered to, and a meal or meals given at the same times every day. Dogs require vitamins A and D and B complex. There are several ways of administering these, but the special commercial preparations, including the modern form of condition-powder tablet, are the most convenient.

The pregnant and lactating bitch require special consideration. The food requirements are very much increased in a bitch which is carrying puppies, especially towards the end of the period. Normally, appetite is not a complete guide to a dog's food requirements, but in pregnancy and lactation the bitch must not be allowed to go hungry. It is quite normal for a heavily pregnant bitch to require over one and a half times her normal amount of food, and in lactation her requirements will increase still further. Milk is a most excellent article of diet at this time; indeed, there is no better way (apart from commercial preparations) of replacing the milk which the bitch is giving to her own puppies.

Up to the age of three weeks or so, puppies need have mother's milk only, but at any time after this it is a sound policy to give them additional food, and so spare the mother and also render weaning (at from six to eight weeks) a gradual process. At first a little cow's milk or one of the commercial "dog-milk" preparations may be given, and gradually the puppies should be encouraged to eat solid food. Eggs (if they can be spared), wholemeal bread in milk, or even finely minced meat may be given, at first in very small amounts but later in larger quantities. If this process is carefully carried out, there will be far less trouble at and after weaning time. After weaning, puppies should receive five or six meals a day, and this number may be cut down gradually until two or three only are given to the fully grown dog. (The smaller breeds are fully grown at about a year.) More meat or meat substitutes and milk, and less cereal or vegetable matter, should be fed to the growing dog as compared with the adult. This fact is very important, as the substances present in meat and milk are

required for laying down the growing tissues. It is possible to rear puppies by hand from birth if the bitch for any reason should die. It requires great patience for the first two or three weeks, as naturally the puppies will require feeding once or twice during the night. Special milks for puppies, unavailable for many years, are now obtainable again. Cow's milk requires enriching with fat and sugar to approximate to the composition of bitch's milk. Feeding will have to be done at every two or three hours, and a very useful gadget is a fountain-pen filler attached to cycle-valve tubing. Very small quantities are required for the first two or three days, and a level teaspoonful of milk is more than sufficient for the average terrier at first. Even with the best care in the world hand-fed puppies tend to be weaklings and do not grow as fast as those naturally fed. A foster bitch, if obtainable, is much to be preferred.

### BREEDING OF DOGS.

It is natural for adult dogs of both sexes to wish to breed, and in the case of the female especially it is an excellent thing if one can arrange for a suitable mating to take place. Bitches come "into season" or "on heat" (lay terms for oestrus) at approximately six-monthly intervals, but it is not advisable to breed from the first season, which occurs usually at about eight to nine months of age. The periods of season generally occur between January and March and in early Autumn, but there is no fixed rule. Each season lasts for three weeks. For the first seven days, approximately (pro-oestrus), a bitch does not permit mating, though during this time she is a source of strong attraction to all males in the neighbourhood. At about the seventh to the tenth day the blood-stained discharge, which ushers in the heat, stops; this is usually taken by the breeder as an indication that the bitch will stand to service. If possible, it is always better when puppies are wanted to allow mating to occur more than once. Under natural conditions a dog and bitch are usually strictly monogamous and mate for life, and during the period of oestrus will mate many times. A dog and bitch that are kept together all the time will probably behave naturally, but under domestication both dogs and bitches usually become promiscuous. Many bitches will in fact, once they have accepted service for the first time during oestrus, accept almost any dog on the succeeding days, and the phenomenon of superfecundation, i.e., the production of a litter that is fathered by two males, may occur. It is therefore wise to retain strict control of the bitch throughout the whole of the three weeks or so she is in season. At the end of season the bitch passes into a state of "metoestrus" if she has not conceived.

If a bitch conceives, she carries her puppies for a period of about nine weeks. There is, however, a normal variation of fifty-eight to seventy days, and puppies born before the fifty-eighth day sometimes live. The number of puppies born varies with breed; in the smaller terriers it is usually from four to six, but in Alredales and Alsations the number may be eight to ten, and the larger breeds tend to have even more offspring at a time. Birth usually takes place fairly easily in the larger breeds, but there is often much difficulty in the case of the short-legged breeds, such as Scottish and Sealyham Terriers, Pekingese and Dachshunds.

A short while before her puppies are due, a bitch will "make her bed." Owners are often amazed at the destruction of soft furnishings, or even of wall-paper, that a previously well-behaved bitch may carry out at this time; it is therefore by far the best to provide a suitable box (if the animal has not one already). A smooth flooring such as a strip of linoleum serves for the bitch to give birth to her puppies. Her instinct to tear up everything given to her for bedding may lead to suffocation of the puppies by pieces of bedding. Provided labour occurs in a warm room, it is better to remove each puppy as it is born, placing a warm bottle underneath, and bring it back to the mother when the last birth has occurred. At this time the bitch should be watched carefully for any discharge from the vulva or for any evidence of straining. If either of these occurs without

results, it is advisable to send for help as early as possible, especially in the case of the smaller breeds. Many hundreds of bitches are lost through neglect at this time, and usually because it was not suspected that anything was wrong. If the discharge becomes bloody, or green, help should be obtained *at once* if no puppy is delivered. Similarly, any great delay between births is a matter for concern. The afterbirth usually follows the puppy within a few minutes, but puppies are sometimes delivered in their foetal membranes, and in this case the latter should be gently but quickly removed. It is quite normal for the umbilical cord to remain attached to the puppy, but the bitch will normally break it by biting through it.

The mother will wash and attend to the newborn puppies, and after the last is born it is a good idea to burn all the mess and to provide clean newspaper, but do not worry or frighten the bitch more than is necessary. For the care and feeding of the bitch and her puppies see the sections on Management and Feeding. Puppies, like kittens, are born with their eyes closed, but open them after about nine days.

The phenomenon of pseudopregnancy is common in bitches, and indeed to a minor degree it is probably present in most bitches following an oestrus without conception. In some bitches, however, presumably those with strong maternal drives, the changes in the ovary may be accompanied by external signs of "phantom" or "ghost" pregnancy. These may include not only enlargement but actual functioning of the mammary glands, and the making of a "nest" by the bitch just as if her puppies were really due. The average duration of pseudopregnancy is usually given as about two months, and although variable, it is often sufficiently near to the correct time after oestrus that everyone suspects the bitch to be truly pregnant. The condition may be suppressed with the aid of modern drugs, but in some instances it is not realised that the condition is not real. In many cases only professional advice can solve the mystery, and X-rays have often proved necessary to ascertain the truth, particularly in fat bitches of the heavier breeds. It might be well to note, at this point, that there is another condition of the older bitch that is known as *Pyometra*. This condition usually reveals itself at the same time as the ghost pregnancy, but is accompanied by considerable disturbance of health, coupled in many instances with purulent discharge from the vagina. A bitch which is off-colour in the weeks following pregnancy, or which develops a discharge from the vulva (especially one which is dark in colour), may well be a pyometra subject. The disease is most serious, and usually requires surgical intervention. As the best chance of success is to operate early, a veterinary surgeon should be consulted immediately.

#### DISEASES AND INJURIES OF THE DOG.

**Canine Distemper and "Para-distemper"** (Including so-called "Hard-pad").—It has long been recognised that the commonest and most serious disease of dogs throughout the world is canine distemper. Dogs of all ages and breeds are susceptible, and no dog is free from the risk of infection unless it has recovered from the disease or has acquired an immunity for other reasons. (For a definition of "immunity," see Medical Dictionary.) The disease is caused primarily by a minute agent known as a filterable virus (see definition of "viruses" in Medical Dictionary), which may be of varying type in that it will attack the body in different ways. Thus some strains of the virus are known as "neurotropic" because they show an affinity for the nervous system. Sometimes a dog will apparently recover from an attack of distemper, only to succumb later to "fits" or other nervous manifestations due to permanent damage to the central nervous system by the virus. Often, however, the virus is not fatal in itself, but will lower the dog's resistance and permit the entry or the activity of bacteria that may lead to pneumonia or other serious effects. These so-called "secondary invaders" as the bacteria are

work it is too late to expect the best results from the use of serum, and whether or not the dog will live through will depend upon the severity of the attack, the dog's powers of resistance, and good nursing. It is therefore most important either to prevent the disease by vaccination or to be able to send for veterinary attention (and hence for an injection of serum) *immediately* an attack is suspected. Any puppy which is listless or off its food, or which may throw a fit, or which is obviously unwell with other symptoms (*e.g.*, cough or diarrhoea) may well be in the early stages of distemper, and it is *then* (not the next day) that help should be sought. Many thousands of puppies (and older dogs) that have been injected with serum in the early stages of the disease have become perfectly normal within forty-eight hours. On the other hand, the number of dogs that die in Great Britain alone from distemper and distemper-like infections must assume enormous proportions. Distemper is a highly infectious disease, and it is important that the owner of an infected animal should do his best to avoid contact with other dogs, ferrets, or mink. Ferrets and mink are very susceptible to canine distemper. On the other hand, human beings and cats are *not* susceptible to canine distemper, and the so-called distemper of cats is quite a distinct disease.

A highly satisfactory means of vaccinating puppies against distemper was worked out about 1926-30, and this—named the "Laidlaw-Dunkin" after its two inventors—has since afforded protection to thousands of animals. Vaccination consists either of the "vaccine-virus" method, in which a vaccine (see Medical Dictionary) is injected first, followed usually after about fourteen days by an injection of the virus, or of the "serum-simultaneous" or "serum-virus" method, in which a puppy receives two injections on the same day, one of virus and one of serum. Other means of conferring immunity have since been developed, including the injection of modified virus, *i.e.*, virus that has lost its power to produce disease but has not lost its power to call forth the antibodies that protect against the infection. A suitable modified virus is now grown on developing egg embryos.

There have, from time to time, been reports of "breakdowns" in dogs vaccinated against distemper. Sometimes these may have been due to the fact that the organisms that act as "secondary invaders" in distemper may sometimes set up disease on their own account should resistance be lowered from other causes. It has become increasingly realised, however, that many such breakdowns were due to an infection which, while closely similar to canine distemper—and in all probability a variant of it—was sufficiently different not to be controlled by the antibodies to ordinary canine distemper. From the fact that one of the features often seen in such cases was the presence of corn-like lesions on the pads of the feet, this infection has been termed "*hard-pad*." The term is not really very suitable, for hard pads are not a constant feature and do not appear until the disease has been active for some days. The earliest symptoms are often nervous in character. "Hard-pad" can, of course, attack unvaccinated as well as vaccinated dogs of almost all ages and since the war it has probably been more common in Great Britain than "ordinary" forms of distemper. A suitable method of vaccinating puppies is now available for use against both the forms of distemper, *i.e.*, protection is afforded against the "hard-pad" as well as the other type. This vaccine, prepared from virus grown on the developing egg embryo, is now widely employed in place of the Laidlaw-Dunkin methods described above.

**Rubarth's Disease.**—Another virus disease of dogs (and foxes) is known as Rubarth's disease, after one of its discoverers, or sometimes as infectious hepatitis. This disease has been recognised in Sweden ever since the 1930s, but in Great Britain only since the end of the war. The condition is extremely sudden in onset, and an affected dog may be found dead. Many cases are, however, mild, and in some instances only one or two out of a large group of dogs have been affected. The changes seen after death vary, but the findings in the liver cells are usually character-

Medical Dictionary) may prevent the effects of secondary infection.

Canine Hysteria (called "fright disease" or "running fits" in the U.S.A.) is an alarming but not necessarily serious condition (in that it can often be cured very readily) which appears to arise from a variety of exciting causes. The affected animal rushes around wildly, often screaming and howling, and obviously loses all sense of whereabouts or ability to recognise people. After a more severe attack (and there are all degrees up to a full epileptiform fit) the dog may appear quite exhausted, but returns to normal. Sometimes there are many attacks in one day. The dog will not wilfully attack people during a bout of hysteria—at least, that has been the experience of the writer—but is very difficult to control. Apart from ensuring that the dog does itself no grievous bodily harm, there is little that can be done until the attack has subsided. Then the animal should be kept as quiet as possible and given a sedative such as potassium bromide, of from 10 to 60 gm. (i.e., from two to twelve 5-grain tablets), pending veterinary attention.

Hysteria may be an hereditary taint, derived from one or other parent. In certain circumstances, however, it may arise in apparently normal animals. There are several possible causes (including parasites), but a definite one is the bleaching agent—nitrogen trichloride or "agene"—employed for some years in the manufacture of flour, and hence present in white bread and certain dog biscuits. Indeed, the clear demonstration that agene could set up hysteria in dogs, and subsequent scientific work, has led to the introduction of regulations that will lead to its abandonment as a bleaching agent in favour of other methods which have been found not to cause hysteria. There has already been a marked decline in the incidence of hysteria due to dietary factors.

Rabies is a fatal disease of dogs, and is also due to a "filterable virus." It is transmissible to the human being and to many other species, but has fortunately been absent from Great Britain for many years. Stringent precautions are taken to prevent its entry, and dogs which are brought into Great Britain must spend a long period in quarantine.

Tonsillitis appears quite frequently in dogs, and seems in many cases to be part of a more generalised infection. It demands expert treatment, but although it may persist for a long time, it usually yields to treatment.

Nephritis.—Inflammation of the kidneys is unfortunately all too common in dogs, and in adult males in particular there is a high incidence of chronic kidney damage. One of the symptoms is a marked thirst. Sometimes this condition is a sequel to an infection known as *leptospirosis*, which calls for prompt veterinary treatment if death or permanent damage is not to follow. It is always worth while seeking professional advice for a dog that drinks excessively.

Anal Glands, which are found in the dog and in other carnivora, often give rise to trouble. Animals which "rub themselves along the ground" are not necessarily affected with "worms," but with impaction of these two little glands, which are situated one on each side of the anus. They secrete a peculiar, dark-coloured, very offensive fluid, which sometimes is not discharged properly and causes the animal great discomfort. The glands in such cases should be relieved periodically. Those who do not mind this somewhat dirty task may perhaps learn how to do it themselves. Occasionally, segments of tapeworm are responsible for the impaction, but usually the trouble has nothing to do with worms. Whenever a dog pays considerable attention to his anus, this impaction should be suspected. Actual infection of the glands is also fairly common, and demands expert attention.

Diseases of the Ear, especially of the outer ear, are very common in dogs. The dog's outer ear is somewhat more complicated than is our own, and the drum is set more deeply. Hence it is easy for wax and dirt to accumulate, for various parasites to establish themselves, and for inflammatory conditions to result. The word "canker" (which has no precise meaning in

more serious or chronic forms of inflammation of the outer ear canal. It is not difficult to diagnose "ear trouble," as the affected animal usually shakes its head or worries or scratches its ear and rubs it along the ground. The ears should be inspected regularly to see that there is no great accumulation of wax or dirt. Cotton-wool twisted on to the end of a match-stick or orange-stick is quite satisfactory for cleaning out the ear, providing care is taken. A dog which is continually worrying its ear, or which has ears which are obviously diseased, should not be neglected, as the sooner expert treatment is begun the more readily will the condition be cured. Even if the lining of the ear is greatly thickened through inflammatory reaction, and the lumen nearly occluded, it is still possible for a plastic operation to be performed. Many hundreds of such cases have been successfully treated in this way. A considerable percentage of inflammatory conditions of the outer ear is associated with ear mange mites. Possibly 50 per cent. of cases in dogs in Great Britain have a parasitic origin. In such an event treatment with modern anti-mange preparations should be carried out.

Deafness in certain white dogs (e.g., in some Bull Terriers) appears to be hereditary, and is quite incurable. Old dogs often become deaf, and deafness has been produced experimentally in young puppies by feeding them on a deficient diet.

Diseases of the Eye are very common in dogs, and are often the result of injury. Except for minor discharges from the corners of their eyes (and in younger dogs especially it must be ascertained that these are not a symptom of distemper or secondary infection) any eye disease is sufficiently serious to merit professional advice. Boracic lotion is not suitable for the eyes of dogs. It is slightly irritant, and dogs are apt to scratch and make the eyes raw after application. Colloidal silver eye lotions and ointments are far more suitable pending the advice of a veterinary surgeon. In eye inflammation avoid sunlight and wind. For some days in the early stages of inflamed eyes, the light in the room should be subdued. Pekingese seem to be especially prone to eye disease, but the remarkably unwholesome appearance of some affected eyes in this breed is not necessarily evidence that recovery is unlikely. Steps should be taken to ensure that the dog does not inflict further injury on an already diseased eye. Cat scratches are a frequent source of inflammatory conditions of the dog's eye. Eyes must never be neglected, for the consequences are serious.

Skin Diseases are common in dogs, and may be contagious—as they are in the majority of instances—or non-contagious. Apart from the inflammation of the skin that occurs in spring and autumn, during the shedding of the winter and summer coats respectively, by far the commonest cause of diseases are the skin parasites: fleas, lice, and mange mites. Owners are often horrified to learn that their dogs are infested with these creatures, and in a few cases filthy home surroundings will lead to the dog being infested with the human kind of flea. Far more often he has his own particular variety of flea, and there need be no shame on the part of the owner. Moreover, many fleas, such as those of the rabbit, the rat, and the hedgehog, will transfer themselves to the domestic dog during his peregrinations. Treatment of these parasitic diseases has been revolutionised in these last few years by the use of modern preparations such as D.D.T. and benzene hexachloride (Gammexane); the latter after one or two applications at about a week's interval, has proved effective for fleas, lice, and mange mites. Apart from those obvious infestations of fleas and lice, skin complaints of a persistent nature, of which the cause is not obvious, should be placed in the hands of a veterinary surgeon.

Diseases of the Teeth are very common in household dogs. A serious systemic disease, such as distemper, may leave the enamel of the teeth permanently pitted, hence "distemper teeth." More serious than this, however, is a form of pyorrhea, which is really a disease of the gums rather than a primary disease of the teeth them-

dition progresses the teeth may become loosened. Particles of food become lodged between the teeth or between teeth and gums, and add to the inflammation and to the smell of the breath.

This disease may, if unchecked, become very serious. In many cases extraction of one or more teeth is indicated, but unfortunately it is not always possible to do this. The condition demands expert attention.

Another common condition of dogs' teeth is the deposition around them of "tartar." This should be removed by scaling or by special use of dental forceps. Some breeders and others may themselves have learnt how to carry out these operations with the requisite skill and care, but they are not easy to the amateur, and it is essential that no harm be done to the animal's soft tissues by injudicious use of the instruments. Ordinary dog-owners are strongly advised to take their dogs to a veterinary surgeon in order to have the "tartar" removed.

Most puppies lose their first or "milk" teeth quite regularly between the ages of three and five months, but sometimes there is difficulty and the primary teeth are not shed properly. These cases should be treated by a veterinary surgeon before the permanent teeth are thrown out of their proper alignment.

One hears very much about "teething fits" in puppies, and while these occur, owners should be very careful to ensure that a "teething fit" is not a sign of distemper, which often starts with a fit. As puppies of this age are so susceptible to distemper, it is advisable to seek professional advice should any form of fit occur. It may save much time, money, and trouble, and even the animal's life.

**Internal Parasites: "Worms."**—It is probable that more nonsense has been talked and written about "worms" in dogs than about any other canine subject. According to some people, "worms" are the root of nearly all doggy evil, and so long as a dog is regularly "wormed" all will go well with him. These beliefs are frankly absurd. The real facts are very different, and are stated in as brief a fashion as possible in the following sentences. In this country dogs are infested by a species of "roundworm" (a creature which is a dirty-white colour and in shape somewhat resembles the common earthworm) and by several species of "tapeworm," which are also whitish but which are flat and are made up of many small segments joined to a little "head" which is attached to the lining of the gut. In spite of all that is said, tapeworms as such are rarely responsible for much harm to the dog. They are a nuisance, and attempts to remove them should be made by administration of the appropriate drug. Occasionally, segments of worm are responsible for impaction of the ducts of the *anal glands* (see above).

The roundworms are much more dangerous to young puppies, although once over the danger period of four to eight months of age, a dog will rarely suffer much from them. It seems probable that puppies are sometimes infected before birth from their mother. From all that has been said above owners will realise the necessity of taking professional advice about young dogs which are ill, and any signs of "worms" in young puppies—either in the stools or by some obvious intestinal upset or bloated appearance of the belly—should be acted upon. One last word about this aspect of worms—do not assume that your adult dog has "tapeworms" unless you see some evidence in his stools. There are so many "signs of worms" that veterinary surgeons must at times get a little tired of being assured that "My dog has worms" because of some trivial habit connected with appetite.

There is, however, another side to the study of tapeworms, and one which is not generally realised. The tapeworm which is found in the dog represents one stage in the life-cycle. The eggs, which are present in the ripe segment passed by the dog, develop, not in the outside world, but in another animal altogether. Thus one of the commonest tapeworms in this country has an intermediate stage, as it is called, in the flea, and it is when the flea is eaten by the dog that this intermediate stage develops further to become a tapeworm. Another tapeworm has an intermediate stage which develops in the sheep, and

a third has one which develops in the ox. There is a fourth tapeworm which has an intermediate stage which may develop in man; to set up serious diseases in certain cases. Children may become infected through handling the dog, and so picking up the eggs, which may then be eaten through putting the hands in the mouth. The dogs which are most likely to be infested are those which have the opportunity to eat freshly killed sheep and other food-animals. An ordinary household dog is not likely to be infested, and people should not worry unduly in this connection, providing they do not allow their dogs to stray into the wrong places. It is illegal to allow dogs to enter a slaughter-house, but unfortunately one has often seen dogs in such places.

**Tumours, including malignant tumours ("cancers")** are relatively very common in the dog—probably as common as in the human subject. Space does not permit of a detailed account, but the following examples of growths may be mentioned: a proliferation of warts on the skin of puppies (usually disappear spontaneously); a true cancer of the tonsil in middle-aged and older dogs of both sexes; cancer of the mammary glands in bitches (both incurable); fatty growths of the vagina of bitches (amenable to operation).

Space does not allow of the discussion of other diseases, but it should be pointed out that dogs are susceptible to human and bovine forms of *tuberculosis*, especially the former. In a household which contains a tubercular person, the dog should be watched for any signs of illness, and the thought entertained that he might be responsible for the further spread of the disease. For a discussion on ringworm see the appropriate heading in the section on the cat (p. 959).

**Accidents and Injuries.**—In these days of swiftly moving motor transport, street accidents to dogs are extremely common. Many could be prevented by training the animal to walk to heel, by the use of a lead in busy thoroughfares, and by not allowing dogs to roam the streets unaccompanied—a thoroughly bad habit. Sometimes the victim escapes with a scare and a few bruises, and at others death is mercifully swift. In the vast majority of accidents, however, a more or less serious injury is incurred, and if the animal is unable to move, the police should be notified immediately. The dog is best left quiet, and it is not recommended that attempts be made to administer brandy or other supposed "stimulants" unless help is markedly delayed. Excessive hæmorrhage may in some instances be prevented by common-sense application of principles learnt in first-aid courses.

One of the commonest accidents to dogs, especially to young dogs, is a fracture involving the head of the femur, or thigh-bone. Inability to put one of the hind legs to the ground, or to bear any weight on this limb, is an indication of such an injury. (This injury may occur also from falling off a chair or wall.) Professional help is, of course, required in such cases.

**Cuts and Bruises**, if not serious, may be treated at home as in the case of human beings. The indiscriminate use of tincture of iodine is not to be recommended, and spirit alone makes a more satisfactory dressing in most cases. Simple washing and removal of dirt are usually sufficient. The dog (and also the cat) are very liable to sepsis, and it is best in such cases to send for proper assistance early, or there may be grave trouble. It is probable that in nature many of the flesh-eating animals end their lives as victims of the sepsis following wounds.

Injuries from cat-scratches are exceedingly common, as are bites from other dogs. These are serious, as they more readily result in septic places. The scratch or bite sometimes penetrates quite deeply, leaving a pocket which fills up with pus. This pus may spread under the skin to form sinuses. Never neglect such places.

There are a few concluding remarks on the treatment of the diseases of the dog:—

(1) It is not correct that "water should be withheld from a sick dog." It is true that an animal which is using water only to vomit, or which is drinking excessively, should have its water intake restricted, but it is wrong to deprive a dog altogether.

(2) There have been such wonderful advances

in the field of veterinary anaesthetics that there is nowadays little to fear in this connection from operations to dogs and cats. The records over the past few years at the Royal Veterinary College, London, have been most encouraging, and the anaesthetic risk is now small indeed.

(3) When a dog's life is a burden to him, it is unfair to keep him alive, and he should be put to sleep. It must be realised, however, that putting a dog to sleep is a very skilled task. It is made much easier if an owner will allow his veterinary surgeon to administer an anaesthetic and not allow the animal "to come round," and shooting is also straightforward and painless if *skillfully* carried out. There are no "magical ways" of destroying human or animal life, and an owner must not expect his veterinary surgeon to be able to bring about death merely by holding a pad to the dog's face. It is far better that the task be carried out at a veterinary surgeon's own premises, where there is skilled assistance.

## CATS.

Many of the general remarks in the preceding section apply equally to cats, and will not be repeated unnecessarily in the following paragraphs.

### BREEDS AND VARIETIES OF CAT.

The following breeds and varieties are recognised for registration purposes by the Governing Council of the Cat Fancy:—

#### Long-haired Cats.

Black	Tortoiseshell
White (Blue-eyed)	Tortoiseshell-and-White
White (Orange-eyed)	Blue Cream
Blue	Brown Tabby
Red Tabby	Chinchilla
Red Self	Smoke
Cream	Silver Tabby

#### Short-haired Cats.

Black	Spotted
White	Russian Blue
British Blue	Manx
Cream	Abyssinian
Tortoiseshell	Siamese (Seal-pointed)
Tortoiseshell-and-White	Siamese (Blue-pointed)
Silver Tabby	Siamese (Chocolate-pointed)
Brown Tabby	Burmese
Red Tabby	
Mackerel-striped Tabby	

Pedigree breeding and showing are practised with a very small fraction of the total cat population of Great Britain, and the majority of these remarks will be concerned with the ordinary household cat. Nevertheless, in recent years there appears to have been a considerable increase in pedigree cat breeding. Registration—which is essential for showing and pedigree purposes—is controlled by the Governing Council of the Cat Fancy, of which the secretary (1952) is W. A. Hazeldine, 1 Roundwood Way, Banstead, Surrey. Many of the breeds listed above have their own societies, which are affiliated to the Governing Council. The addresses and particulars of these and other cat societies and clubs may be had on application to the secretary of the Governing Council. The two most popular varieties of cat are the Blue Persian and the Siamese, and in peace-time an exclusive show is held for each of them. In addition to these shows there are five big Championship Shows open to every variety of long- and short-haired cat, while there are classes for cats and kittens at some of the Agricultural Shows.

### CHOICE OF CAT.

Although there are, as noted above, many varieties of cat, most people are content to accept an ordinary kitten, and for them the chief points to consider will be: (a) whether to have a long-haired or a short-haired animal, (b) whether to have a male or female, (c) whether or not to have the kitten "doctored" (i.e., castrated or spayed). As a general rule, short-haired cats are probably more suitable for the average household, since their fur does not become shed so noticeably and they probably suffer less from "fur-balling." Nevertheless, many long-haired cats are so

attractive that they will obviously be preferred, and there is no reason why they should not be chosen. Sex is a rather more important question, although, as may be seen in the section on management, it is possible to have both males and females "doctored." Male cats which are kept as entires are often a nuisance in that they make abominable smells in the house and spend much of their time in fighting. These characteristics are by no means invariable; but they are so common as to justify the castration of the majority of males. Females are generally credited with a greater attachment to the home (although they wander when "in season") and with being better mousers. The principal objection to females is that they seem to be bearing kittens almost continuously. In normal circumstances it is, of course, quite impossible to prevent cats from mating by keeping the female in confinement during her season, a practice which is frequently adopted in the case of the dog. For one thing, most people are never aware when their female cats are in season.

Whatever animal is chosen, it is essential to pick a healthy and preferably a fairly young—but not too young—kitten. It is best not to accept a kitten under eight weeks of age.

For those who wish for something a little out of the ordinary, Siamese cats make excellent and highly intelligent pets. Siamese kittens are born white, but gradually develop their even pale fawn colour, with cream on belly and chest and with "seal brown" mask, ears, legs, feet, and tail. The coat is very short, and the eyes are blue. There has long been a popular belief that Siamese cats are delicate creatures, but the present writer has seen healthy specimens, kept under ordinary household conditions, living to a mature age. It is not wise to keep a male Siamese as a household pet. The male is a fierce fighter, and is generally a worse offender in the house than the males of other breeds.

Many people find Manx cats attractive. Instead of the normal large number of tail bones, they have but three, and hence appear almost tailless. One should beware against fraudulent amputation of the tail of ordinary cats, which are then described as "Manx."

### MANAGEMENT OF THE CAT.

The cat is an independent creature, so much so that one may say that to a large extent it manages its own affairs. This, however, is not true of all cats, and every reasonable attempt should be made to provide the cat with a comfortable and friendly home. Cats are highly intelligent, and if sufficient patience is exercised they will respond to a very great degree to human attention. Kittens should not be neglected, but should be talked to and played with just as are puppies. Many cats, especially young cats, make excellent playmates for children.

In order to prevent to a large extent their nocturnal wanderings, many cats of both sexes are castrated or spayed (the popular lay expression for this is "doctored"). In the male cat the testicles are removed by an operation which is almost always safe and simple if carried out skillfully. From three to four months is a good age at which to have this done. Female cats may also be "doctored." As the female glands or ovaries lie within the body cavity, this operation is a major one, but it is nevertheless quite a straightforward, though a more expensive, procedure if conducted at the right age (about five months). Many thousands of female cats have been so operated upon at the Royal Veterinary College, London, and the subsequent health of these cats is believed to have been excellent. Indeed, it has been said that a spayed female makes one of the best of all household cats.

Cats may choose to sleep in a variety of places, and will often lie on beds, chairs, mats, and other warm places. It is a sound policy to provide them with a box or basket, and to encourage them to use newspaper as a bedding. Most cats will take well to newspaper. The bed should be placed in a warm site—it is of little use putting it in a cold corner of a room and expecting the cat to lie in it.

Owing to the fact that, even in play, a cat's claws may inflict serious injury, dogs and cats do not always make the best of house companions.

Nevertheless, the traditional enmity of cat and dog is often overcome, and if the two are brought up together they often make firm friends, sharing the same basket or hearth-rug and feeding together without serious consequences.

A cat normally attends to its own toilet, and everyone must be aware that a cat devotes long periods each day to cleaning and washing itself. Except in special cases, therefore, bathing is quite unnecessary, while in short-haired cats especially, grooming, too, is superfluous (this does not apply to show-cats). For some reason (and sometimes, apparently, because an owner attempts to assist in the daily grooming) a cat may cease to wash or care for itself. Such an animal is a dejected sight, and should be taken to a veterinary surgeon to have its matted fur cut or combed, and its dirt removed. Such animals (unless they completely re-acquire their self-respect) must be groomed regularly if they are to be kept at all.

All household cats are accustomed to take their own exercise, and it is advisable (except in any special circumstances) to allow them free access to and from the outer world. Do not shut your cat in the house for a long period and then blame it for making a mess. Cats are clean creatures; they normally dig small holes in which to defecate or urinate, and subsequently cover the deposit with earth. If, therefore, they are for some reason debarred temporarily or permanently from access to a garden, they should be provided with a box or tray containing soil or cinders. Indeed, in many types of houses it is a good plan to encourage kittens to use such a device. (Note the corresponding remarks about puppies.)

It is generally stated that "cats never forget a blow," and for that reason it is recommended that cats are not chastised. It may be said that, if a cat (or dog) be brought up conscientiously and well, it should never, or very rarely, require such punishment. An animal which has been brought up properly knows what is right and what is wrong.

For pedigree cats, or those kept in confinement for other reasons, see the relevant remarks in the section on breeding.

#### FEEDING THE CAT.

Although most cats are capable of supplementing their diet by catching small rodents or birds, it is unwise to rely on this as a regular source of food. The idea that hungry cats make the best mousers is by no means always correct. Indeed, animals that are in poor condition are less likely to be successful hunters. Moreover, while the riddance of pests is an excellent matter from the human point of view—and one of the reasons why the keeping of cats is economically justified—the "cruel" fashion in which most cats tackle their prey is repulsive to most of us.

It is therefore necessary and desirable to provide regular daily feeding. Kittens should receive several meals a day, but by the time they are six months old the number of daily feeds should be reduced to one, or at most two. Most cats (many Siamese are exceptions) are extremely fond of milk, especially if it is creamy, and the cat's love of fish is well known. Many meats, especially rabbit meat, are relished, and a diet high in "animal protein" is indeed the aim, always provided that it contains sufficient "dietary energy." It is significant that cat's milk has a higher content of fat and sugar than cow's milk, i.e., it is a richer source of energy. Some of the proprietary bitch-milk substitutes are nearer to cat's milk in composition than is cow's milk.

Cats are also extremely fond of liver. Some of the proprietary cat foods—the better ones of which are excellent—and vitamin tablets contain liver, which is a rich source of the vitamin B complex.

Within reason a healthy kitten should be fed to appetite, always provided good-quality foods are available. The amount should be restricted when they are adult, however, except for pregnant and lactating cats, which are sometimes referred to as "queens" as opposed to the male "toms." An average daily allowance of solid food for a healthy non-pregnant adult cat should be of the order of  $\frac{1}{2}$  oz. per 1 lb. body-weight.

Cats are fastidious eaters; they usually sniff and examine carefully any strange or doubtful food. At the same time they are often greedy,

especially with relished food to which they are accustomed, but fortunately they can, like dogs, vomit very readily. Here, incidentally, is one very good tip—an excellent emetic for both cat and dog is a small crystal of washing-soda, given as a pill. People are usually amazed at the way this simple device results in a dog's or a cat's bringing up undesirable food.

It is important not to overfeed cats, and it is almost equally important to prepare all food in a clean manner, and to make it as attractive as possible. Cats will greatly appreciate this care. While milk is an excellent food for kittens (see under breeding), and is relished by most adult cats, it must be supplemented by solid food.

Clean fresh water should be provided at all times, even if the cat appears to drink it but little.

#### BREEDING OF CATS.

Pedigree animals are normally confined, and their breeding is strictly controlled. Ordinary household cats are at the opposite extreme, and there is little that can be done to prevent their mating. The length and scope of this article does not permit of a discussion of controlled mating.

Scientifically, there is as yet a good deal to learn about the reproductive behaviour of the cat. As an American physiologist has succinctly put it in a description of the reproductive cycle of the female cat, "No two authors agree." In Northern Europe there are two main heat periods a year, in spring and early autumn, but some animals may appear in heat at any time from January to July, and those who keep female cats in confinement describe their charges as "calling" quite frequently if not mated. A cat which is "in season" or "on heat" is often observed to be behaving in a quite characteristic fashion, rolling about on the floor and making peculiar sounds. The periods of heat, which commence usually at about eight months of age, may last for several days, and during this time the female will make every attempt to find a mate.

Gestation lasts about nine weeks, as in the case of the bitch, but here again there is a considerable variation. As most owners are quite unaware of the time at which their cats were mated, it is difficult to talk of "going overtime," but if there is any evidence of trouble during pregnancy, or at birth, veterinary advice should be obtained. As soon as a cat is obviously pregnant, her food allowance should be increased, and she should be allowed plenty of milk. It is highly important to increase her food and milk ration still further after the kittens are born, as lactation is a great drain on the mother.

Cats sometimes choose strange, out-of-the-way places in which to litter, and many healthy litters are born and reared out of doors. Cats are a source of danger, and will often destroy very young kittens during the mother's absence. For this and other reasons it is better in town and suburban areas to have the litter comfortably housed indoors. A wooden box containing newspaper is ideal, provided it is kept in a fairly warm place and out of the way of draughts. An average litter consists of three to six kittens, which are born blind, but which normally open their eyes after eight or nine days. There is no need to be alarmed if the eyes remain closed for a few days longer. Kittens which are born dead should be removed and buried or burnt. If the whole litter is born dead, the mother's food supply should be cut down considerably, and little milk given for a few days. If the mammary glands become inflamed, they may be bathed in a cold solution of alum. The glands normally return to their former size within a short space of time if they are not milked, but if there is persistent trouble veterinary advice should be sought.

While many pedigree owners wean kittens at four to five weeks of age, it is strongly advised that the household cat be allowed to continue to feed her family for a longer period, and eight weeks is not too long if the mother is still in good bodily condition. She must, however, be well fed and be allowed plenty of milk. As in the case of puppies, it is an excellent idea to provide the kittens with a little solid food as from a few weeks of age. It is very wrong to remove a kitten from its mother too early, and such an

animal is often weakly, develops an intestinal infection, and dies as a miserable bedraggled creature. Moreover, during the period following weaning the mother educates her offspring in the art of living, particularly rattling and mousing.

As many litters are unwanted, some people get rid of all the kittens as soon as possible after birth. Drowning is frequently practised, but it is not recommended as a merciful death. Indeed, a hard blow on the back of the head is more humane if given accurately. It is much better to take the kittens to a veterinary surgeon or clinic.

#### DISEASES AND INJURIES OF THE CAT.

The principal infectious diseases of cats are still in need of much scientific study. It is now clear, however, that there are at least two major cat plagues. Both have been given many names, and there is much confusion between them.

**Feline Enteritis or Panleucopenia.**—This is a highly infectious disease, due to a filterable virus, in which enteritis is sometimes (but by no means invariably) a feature. Cases that do not die abruptly show obvious signs with a typical cry of pain when handled, due probably to peritonitis. There is a characteristic fall in the numbers of granular white-cells in the blood—hence “panleucopenia” or “agranulocytosis.” The mortality rate is very high, and unfortunately a serum is not available commercially, although a protective vaccine may be obtained. This is the complaint that is so frequently responsible for a paragraph in the newspapers to the effect that nearly all the cats in a certain locality have died and that poisoning is suspected. On some farms, where, of course, cats are needed as defence against vermin, it has proved impossible to keep them owing to complete extermination of all introduced stock from this infection. More recently attempts have been made to stock such farms with vaccinated kittens. A rather typical symptom, which should be a strong warning to the owner to secure veterinary attention immediately, is that the animal is sitting crouched over a bowl of water or milk without attempting to partake of anything. While specific treatment is unavailable, skilful nursing under veterinary direction may result in certain cats “pulling through.” Great care must be taken to avoid dehydration, *i.e.*, loss of body fluids without replacement. Liquids must therefore be provided.

**Feline Pneumonitis.**—This disease is sometimes termed “cat distemper”—as indeed is feline enteritis—but neither condition is the same as canine distemper or transmissible to dogs or to human beings. Feline pneumonitis affects principally the respiratory tract, and is characterised by a copious discharge from the eyes and nose. It is due to another filterable virus, which paves the way for “secondary invaders,” but provided good nursing, warmth, and light nourishment (including liquids) are given, the death-rate is low. Neglect or lowered powers of resistance may, however, result in a fatal pneumonia.

**Tuberculosis.**—The cat, like the dog, can contract tuberculosis, but so far as is known only the bovine form has been known to infect it. The infection usually comes, of course, from milk, and the increase in pasteurisation will tend to reduce the incidence of the disease in cats. The disease commences in the abdomen, but may spread to the lungs. There is general wasting.

**Skin Diseases.**—As in the case of the dog, skin disease in the cat is usually of parasitic origin, and fleas and mange mites are again the chief source of trouble in Great Britain. Cats do so much of their own toilet that the average household cat has probably a cleaner skin than its canine counterpart. When skin disease does develop, it is strongly advised that the animal be taken to a veterinary surgeon for appropriate treatment. As a rule cats greatly resent the interference which must accompany any attempt to bathe or dress an affected place, and for this reason it is usually unwise for an owner to attempt to do other than make an inspection. Very small patches of skin eruption may clear satisfactorily if the surrounding hair is clipped away with curved scissors, but generally speaking skin disease calls for professional attention.

**Diseases of the Ear.**—The outer ear of the cat is frequently affected, and in a great many cases a

form of mange mite is responsible. The animal provides evidence of the trouble by scratching and shaking its ear and generally showing its discomfort. It will not always be possible for an owner to make a thorough examination, as in many cases the cat objects, but if it is possible to look inside the ear it will be seen that there is a dirty and usually brownish mess of tissue, sometimes mixed with dried blood or pus. Not all cases are as bad as this, of course, but if a cat persistently worries its ear it should be taken to a veterinary surgeon. There are satisfactory dressings for this condition, and owners will be able to dress their cats if the latter are docile. Otherwise it is necessary to have the ears dressed by a veterinary surgeon or by one of his staff.

A cat's ear is frequently the site of a blood blister, or hematoma. This is usually the sequel to a blow, such as a slamming door, and shows itself as a large, tense swelling, which when opened by the surgeon proves to be an accumulation of serum usually tinged with blood. Some cases become infected at the time of injury, some after with the patient's rubbing. With the greatest surgical skill in the world one must expect a slight deformity, and the cat develops a puckered ear, much the same as the human boxer.

**Disease of the Bladder.**—The bladder is a common seat of disease in cats, and is frequently affected through the blocking of the natural water-passage by small sand-like calculi. Naturally, male cats are more often affected, as the terminal end of the urinary tracts is wider and more dilatable in females. The urine is unable to escape, and the bladder becomes filled with a mixture of urine and the sandy calculi matter. The condition may be diagnosed quite readily, as the cat usually collapses, or partially collapses, and one may easily feel the distended bladder through the walls of the abdomen (belly). It is necessary to send for professional help immediately, and, while no relief can be guaranteed, it is often possible to relieve the condition by judicious manipulation. Owners should not attempt to do this themselves (unless help cannot be obtained), as they may easily burst the bladder. As the animal is usually in a state of collapse when the condition is discovered, it makes a bad risk for actual operation, and relief by skilled pressure is usually to be recommended.

**Ringworm.**—There are two common kinds of ringworm in the cat (a third, which may also infect the dog, is more rare; it is the trichophyton which is usually found on cattle). The first kind is acquired from rats and mice, and is most commonly to be found at the bases of the claws, from where it may spread to the ears and face. The individual lesions are circular and yellow in colour, and consist largely of a scabby material. This kind of ringworm is known as “favus.”

The second type of ringworm (microsporon) is more important, because it is more readily transmissible to human beings. Whereas this form usually sets up circular scaly lesions in the dog, it often infects cats without there being much naked-eye evidence of its presence. Indeed, in the cat the condition is often unsuspected until the owner himself becomes infected and consults his doctor.

Ringworm should be treated or dealt with by a veterinary surgeon, who will also confirm or refute by special methods the presence of microsporon in cats.

**Intestinal Parasites**—“Worms.”—The cat also is subject to both roundworms and tapeworms. The roundworm which parasitises cats in this country is similar to that of the dog (although a different species) and is also much more harmful to the young than to the adult animal. In kittens the symptoms are a general unthriftiness, staring coat, and in some cases diarrhoea and a “pot-bellied” appearance.

The commonest cat tapeworm in this country is one which passes its intermediate stage in the rat or mouse, or sometimes in other rodents. The tapeworm, which, as mentioned under the section on dogs, is dangerous to man, is sometimes found in the cat also.

**Accidents and Injuries.**—Despite their sagacity and alertness in many ways, cats seem curiously unable, in many instances, to acquire road-sense. They are dazed by a car's head-lights, while if a

motorist sounds his horn they tend to stop still in their tracks.

Injuries from traps, *e.g.*, gin-traps, are very common, and it is probable that many thousands of cats annually are maimed in this fashion. Cats suffer injury from shooting, from stoning, and from blows with sticks. Since they are predatory animals, they have often to pay the penalty inflicted on them by wrathful people. Needless to say, cats which survive to return home usually require expert treatment.

Poisoning may be included under this heading. Although there are doubtless many deliberate attempts to poison marauding cats, alleged "poisoning" is often no more than a case of feline enteritis, and owners should not claim glibly that their cats have been poisoned until they have expert evidence to back their judgment.

Fur-balling, as it has been termed, may be mentioned here. Cats, especially the long-haired varieties, must often ingest hair during their toilet, and occasionally serious trouble (a stoppage of the bowels) is brought about by a mass of such hair which has collected in a part of the bowel. There is constipation, loss of condition, and often evidence of considerable pain. Such cats should be taken to a veterinary surgeon.

Bites and scratches are even more common in the cat than they are in the dog, and subsequent sepsis is equally likely.

## FERRETS.

**Description.**—The ferret is probably a domesticated form of the pole-cat (*Mustela putorius*), and is known sometimes by that name and sometimes as *Mustela furo*. Most tame ferrets have pink eyes and yellowish-white fur, but there are darker forms believed to have resulted from crossing in previous generations with wild pole-cats. Indeed, these darker forms are popularly termed "pole-cat ferrets." They are of two main kinds, the first having creamy under fur and black guard hairs, and the second being a chocolate-brown colour, with brown upper parts and black under parts, and a few scattered light hairs on the face.

Ferrets are long creatures in relation to their body weight, and when fully-grown may have a body 14 in. long or more and a tail of 5 in. Some strains grow appreciably larger. The main use of the ferret is, of course, in rabbiting, for which purpose they have been employed for many centuries. Although they can become fierce if not accustomed to regular handling or kind treatment, and are capable of inflicting a nasty bite, they may nevertheless be made into docile and highly intelligent pets. It is most important to win their confidence from the beginning and to accustom them to regular handling from the time they are young "kittens."

**Accommodation.**—Ferrets must have dry, clean accommodation in a room free from draughts but well ventilated. Wood is warmer than metal, but more difficult to clean, and is best lined with hard asbestos sheeting, which is resistant to water. The most suitable accommodation comprises a sleeping compartment of similar proportions to a small kennel, leading by a small doorway or "pop-hole" to a wire-netting exercising run, which should be as large as possible compatible with cleanliness. It is a good idea to have a means of closing the doorway so that the ferret or ferrets may be confined within the sleeping-compartment if necessary. Wood-wool makes an excellent bedding, but if difficult to obtain newspaper may be provided for the ferrets to lie on. The floor of the run may have a false bottom or may be sprinkled with sawdust. It is imperative to keep the whole of the accommodation clean and dry, not only to avoid smell but also to prevent the ferrets from developing a very serious necrotic infection of the feet known as "foot-rot."

**Feeding.**—Many ferrets are unfortunately not fed adequately. It must be appreciated that basically they are carnivorous animals, and that their food requirements are more similar to those of the dog and cat than to those of rodents. Indeed, many of the general remarks made about the principles of feeding dogs and cats apply to ferrets also.

Most ferrets like bread-and-milk, and while this is an excellent article of diet, it is in itself inadequate. Up to about 4 oz. of raw meat (minced for younger animals) daily is an excellent basis, and this may be replaced by fish. Liver, especially raw liver, is an excellent source of many factors, and there is good reason to provide some at least weekly if it can be obtained. Failing this, it is advisable to add 1-2 per cent. of whole dry liver to the diet. Once ferrets are grown, one feeding daily—at a fixed time—is sufficient. The female (jill) should have ample supplies of milk just prior to the birth of her young and while she is suckling them.

**Breeding.**—In the northern hemisphere the female ferret usually comes into oestrus (season) in early March of the year following that in which it is born. If the jill does not conceive during this oestrus she will have a further oestrus period in July or August. The desire of the jill to mate is very strong, and if not allowed to do so, some animals sometimes have been found to waste and pine. The act of mating is prefaced by very vigorous behaviour on the part of the male (hob), and anyone not appreciating the performance might think that he was out to kill his mate! The mating act itself is usually prolonged, and may take up to three hours. If left together the hob and jill will probably mate from two to four times during the course of a couple of days. As in the cat and rabbit, ovulation or the shedding of the egg from the ovary takes place as a result of mating, and not spontaneously. The period of gestation is forty-two days, and the number of young born usually varies from five to thirteen, the average litter being six to eight. Pseudo-pregnancy occurs if the jill is not mated, and may become outwardly obvious as in the case of certain bitches.

Males also have a seasonal rhythm, their capacity to fertilise being greatest from early March to August. Young hobs seem to be active about a month earlier than older ones. The length of daylight or, rather, the incrementation in light from day to day, has an important bearing on breeding capacity in both sexes, and by the use of artificial light it has proved possible to induce either oestrus or male activity at different times of the year.

The young are hairless and blind, and weigh on the average under  $\frac{1}{2}$  oz. at birth. Their eyes open at about four weeks, and they can then commence to eat small pieces of solid food to supplement their mother's milk. They may be weaned at from six to eight weeks.

**Diseases.**—The most serious disease of ferrets is *canine distemper*, and the variant known as "hard pad" (see under dog) is equally capable of infecting ferrets. Such infections can wipe out entire stocks, and every care should be taken to prevent their spread from dogs to ferrets—and vice versa. A veterinary surgeon should be consulted immediately when a ferret becomes ill or out of sorts. Ferrets are also susceptible to some strains of human influenza, and should not be tended by persons with colds or with any indications of "flu." The feeding of infected milk may give rise to *tuberculosis*, and as a safety measure it is better to give only tuberculin-tested or pasteurised milk, or milk that has been boiled to destroy infection. *Foot-rot* has already been mentioned, and must on no account be neglected. *Mange* or "scabies" of the back and tail region should be dealt with promptly, employing modern preparations. Abscesses of the neck region are often encountered, and should receive professional treatment if they do not clear up rapidly, for they may spread with dire consequences.

## RATS.

**Description.**—Tame rats are domesticated varieties of the wild Norway or "brown" rat (*Rattus norvegicus*). Such rats are usually albinos or black-and-white, although other colours have been bred. The hooded varieties are those in which the head and foreparts are mainly black or chocolate and the remainder of the body, apart from small patches the same colours as the hood, is white. Tame rats differ materially from wild ones in disposition, and properly managed are

extremely tractable. Healthy specimens accustomed to handling bite only when frightened, e.g., when a sudden movement is made in front of them. Males appear to live longer than females, but three years is a good age.

"Black" rats, i.e., the species (*Rattus rattus*) sometimes known as the ship or Alexandrine rat, have been bred in captivity, but tame strains are not generally available.

**Housing.**—Tame rats require a warm, even temperature—65–70° F. all the year round—and draughts or lowered temperature may precipitate lung disease or other disorders. It is best to have a complete spare set of boxes or cages, and to change to fresh quarters weekly except when the females have unweaned young with them. Empty cages should be cleaned and disinfected thoroughly before being used again. Provided the temperature conditions are suitable, metal cages of the types employed in scientific laboratories are best, with wire-mesh false bottoms and trays containing sawdust to catch the droppings.

Accommodation should be ample, and even for a pair of pet rats the cage should measure about 30 in. × 18 in. × 18 in. If wooden boxes are employed it may be desirable to line them with hard asbestos sheeting or galvanised metal to prevent damage from gnawing.

Small, dark "shelters" and exercising devices, e.g., wheels or ladders, are appreciated by the rats, but must be kept clean. Wood-wool makes the best bedding.

**Feeding.**—Rats may take a wide variety of foods, including many of our own, and there are several successful ways of feeding them, including the provision of specially formulated "rat cubes." A good daily diet is wholemeal bread, mixed cereals (e.g., oats, wheat, hempseed), with about

WATER BULB SUITABLE FOR USE  
WITH LABORATORY RODENTS

5 per cent. dried brewers' yeast and milk either fed separately or mixed with the rest of the food. Twice weekly each rat should be given up to  $\frac{1}{2}$  oz. or more of meat, liver, fish, or other "animal protein." A little fresh greenfood (even grass) is appreciated occasionally, and in winter especially some supplement containing vitamins A and D is desirable. Expectant and nursing mothers should have as much milk as they require. Never overfeed or allow uneaten food residues to

remain in the cage. Fresh water (preferably in bulbs) should be available at all times.

**Breeding.**—Rats can breed at quite a young age (usually being capable of mating when fifty to sixty days old), but it is better to separate the sexes within a fortnight or so of weaning (weaning being usually at twenty-one days of age) and to mate at about 100 to 120 days of age onwards. The female rat has an oestrous cycle lasting just over four days. One male (buck) may be mated to one female (doe)—this is probably best in the case of pet rats—or with two or three females if preferred, but it is unwise to keep more than one adult male in the presence of females. The gestation period is twenty-one to twenty-two days, or occasionally a few days longer. The number born varies considerably, but often it is best to try to rear only six to eight young. The young have their ears open at  $2\frac{1}{2}$  to  $3\frac{1}{2}$  days, cut their incisor teeth at eight to ten days, can find their way to their mother at about the same time, open their eyes at fourteen to seventeen days, and may leave the nest at twenty-one days. In the case of pet rats it is probably best to leave the young with the mother for up to a week or so longer. Breeding can occur all the year round, but takes place less readily in winter.

**Handling.**—Rats should not be "tailed," or the skin may slough off. Regular handling after weaning is excellent and promotes docility. The weight of the body should be supported.

**Diseases.**—On the whole rats are much less liable to disease than mice, provided temperature conditions are suitable. The commonest infection is *broncho-pneumonia*, often precipitated through draughts or cold. *Mange* (especially of the ear) and infestation with *lice* may occur, and should be dealt with promptly by means of modern insecticides. Avoid contact with wild rodents, or the use of food or bedding that may have been contaminated by wild rats and mice.

## MICE.

**Description.**—Tame mice are descended from the common house mouse (*Mus musculus*), and it is believed that mice have been domesticated for over 3,000 years. Apart from albino or "white mice," there are many varieties that have been bred by the extensive "mouse fancy," and there is a wide range of coat colour and also different types of coat, e.g., long-haired, short-haired, and rex. "Waltzing mice" have an abnormality of that part of the inner ear concerned with balance. Mice may live up to thirty months, and in exceptional cases attain the age of three years or more.

**Housing.**—Although strains vary, most tame mice require a warm even temperature and the same general remarks concerning temperature range, bedding, and wooden or metal cages apply as in the case of rats. If a solid floor is used, this should be covered with clean sawdust. It is a good plan to change to a clean cage regularly, except when the female (doe) is nursing her young. If the cage is large (as in the case of pet mice it should be, with a floor space of say 24 in. × 12 in. × 12 in. for a group of mice), inner nest-boxes should be provided—one for each doe if breeding is taking place, although two does will often share the same nest-box. (In changing to fresh cages the nest-box, with mother and young inside, may, of course, be moved over.) A "two-storey" cage, with a ladder or "staircase" to the upper part, is an attractive variation, although difficult to keep clean. Mice should be kept well out of reach of wild rodents, from which they may all too readily contract disease.

**Feeding.**—Mice have not quite such a wide dietary range as rats, but there are several different ways of feeding them, including the provision of special "mouse cubes." These mouse cubes are of varying composition. One of the most successful, devised by workers in the Medical Research Council's laboratories, is known as "Diet 41," and is made up of the following parts by weight: wholemeal flour, 45; Sussex ground oats, 40; fish meal, 8; dried yeast, 1; dried skimmed milk, 3; cod-liver oil, 1; and common salt, 1. Diet 41 has also been employed for rats

and monkeys, although for the latter particularly it requires supplementing. It is perhaps worth emphasising that cod-liver oil must not be fed in excess, or it may prevent breeding and possibly have other harmful effects. Cubed diets are best fed from a wire basket through which the mice enjoy gnawing and eventually pulling out the pieces. Wholemeal bread is excellent if not allowed to become stale, but it should not form the sole article of diet, and it is a good idea to feed it alternately with a grain mixture (made up of rolled oats, wheat and other cereal grains, or mixed bird seed). Up to about 5 per cent. dried brewers' yeast is excellent, and so is fresh or dried milk, especially for mothers that are carrying or nursing young. Cheese is relished, but may smell if not fed carefully. Mice also like an occasional pinch of marmalade, and it is a good idea to provide lettuce or other greenfood every week or so. There should be a constant supply of fresh water, preferably from bulbs.

**Breeding.**—Young mice may be weaned at twenty-one days, although it is usually preferable to leave them with their mother for a further week. The age at which mice are capable of mating varies considerably from one strain or individual to another, and while the average is six to eight weeks, it may be much younger. It is therefore desirable to separate the males from the females at or shortly after weaning. Mice may be mated up at two to three months of age, and the best arrangements are one male (buck) to one or two females. A pair of mice or a "bigynous trio" makes a successful combination. The estrus cycle is similar to that of the rat, but its length appears to vary with coat colour, being longest in the brown mice and shortest in blacks and albinos. The gestation period is usually from eighteen to twenty days, but may be prolonged if the female was still suckling her previous litter when she conceived. There may be up to twelve or more young in a litter, but the average litter size is from five to seven. The second litter is usually the largest, and subsequent litters tend to decrease in numbers, so that the sixth is usually smaller than the first. Breeding may take place all the year round, although, as with rats, fertility is higher during the summer months.

**Handling.**—Any rapid or rough movement may frighten mice and cause them to bite through fear. Mice should be lifted by the tail—not too near the tip—and may be held in the palm of the hand, where they may be suitably restrained by keeping the tail between two fingers.

**Diseases.**—Mice are unfortunately prone to many diseases, although the risks will be much lower if they are kept in suitable surroundings, great care is taken to avoid infection, scrupulous cleanliness is observed, and the standard of feeding is good. One common source of infection is the presence of the excreta of wild rodents on bedding or foodstuffs. A common disease is that sometimes called "mouse typhoid," caused by organisms of the *Salmonella* group. Although some mice recover, they may remain carriers of infection, and once this disease is diagnosed it is best to destroy the affected mice and those in contact with them, and not to employ any of the cages or utensils for fresh mice without adequate sterilisation. There are other septicaemia diseases of mice, and also virus diseases, including certain types of *pneumonia* and a condition known as *infectious ectromelia*. The accurate diagnosis of these calls for expert opinion and often for special bacteriological or other examinations. The mouse-owner should, however, be able to recognise signs of ill-health or departure from normal, one of the commonest being loss of appetite. In young mice the coat should be smooth and glossy. As mice get older there may be loss of pigmentation (in coloured mice) or even loss of fur. A sick mouse usually sits hunched up and has a ruffed coat, while the eyes may be partially closed or have some discharge. A healthy mouse will usually catch on to suitable objects when held by its tail and is capable of pulling quite hard, whereas the pull of a sick mouse is much weaker. If one or more mice die it is best to destroy at once any cage-mates that appear sappy. As in the case of rats, external parasites should be dealt with promptly with the aid of modern insecticidal preparations.

## GOLDEN HAMSTERS.

**Description.**—There are many species of hamsters in the world, and more than one kind can now be bred in captivity. The one referred to, however, is the Golden Hamster (*Mesocricetus auratus*), a delightful little creature of which a full-grown female (females are larger than males) rarely exceeds 7 in. in length. The history of the domestication of the golden hamster is quite remarkable, for prior to 1930 only museum specimens were known. In that year a mother and her twelve young were dug up in a field near Aleppo and were taken to the Hebrew University, Jerusalem, and from that one family have been bred the hundreds of thousands of golden hamsters now employed as pets or as laboratory animals in many parts of the world. The species has taken well to captivity and, although capable of inflicting a nasty little bite if frightened or handled roughly, becomes docile and friendly when properly cared for. Characteristic features are the soft, smooth fur, the large black eyes, the "cheek pouches" in which food is stored and which may become enormously distended after a meal, the short, stumpy tail, and the extremely loose skin, inside which the hamster can turn round to a considerable degree.

**Housing.**—The same remarks about accommodation, environmental temperature, freedom from draughts, fittings, and other general considerations (including cleanliness) apply as in the case of rats and mice. For breeding purposes a dark inner chamber or nest-box is desirable. Several hamsters may be kept together, but the introduction of a stranger (or even the re-introduction of a former cage-mate that has been removed for some time) may lead to fighting.

**Feeding.**—Satisfactory diets include the following: (1) rat cubes (e.g., "Diet 41"), carrots, greenfood, and milk; (2) cereal grains and/or wholemeal bread, carrots, greenfood, and milk; (3) steamed Rangoon beans, wheat, maize meal bread, a little Marmite, and milk. Care must be taken not to allow storage of excess food, which will deteriorate and cause a smell. Grass is a suitable source of greenfood during its growing season. Apples and other fruits are often relished. Water, preferably in bulbs, should always be available.

**Breeding.**—Golden Hamsters attain puberty at from ten to fifteen weeks of age, or even younger, males being usually earlier. Generally speaking, it is best to defer breeding until after fifteen weeks of age. There is an estrus cycle of about four days, and the gestation period is very short, averaging sixteen days, although sometimes up to nineteen days. Mating not followed by conception results in phantom or pseudopregnancy. Litter size varies from one to fifteen, but the average is six to seven. Not many females have more than four litters, and although both sexes may live up to two years, breeding by the female is rare after nine months. The young are naked and blind at birth. Hair first appears at five days, and covers the whole body at eight days. The eyes open at about eleven days, and soon after this the young begin to take food for themselves and may be weaned at three to four weeks. Care must be taken that the female does not injure the male, and for safety's sake it is probably better to keep only one female and one male together and to remove the male before the young are born.

**Handling.**—Gentleness is essential, and sudden movements should be avoided. The tail is much too short to use, and the easiest way is to lift them by the loose skin over the back and shoulders. As already noted, they can twist easily within their skins, unless a substantial amount is taken in the hand. After picking up they may be allowed to sit on the palm of the hand.

**Diseases.**—Several diseases of hamsters are now known, and, like most rodents, they are susceptible to *Salmonellosis* (see notes under "mouse typhoid" and "paratyphoid" in guinea-pigs). The main trouble is, however, from *ear mange*, in severe cases of which the condition spreads from the ears to other parts of the body. Modern anti-mange preparations are highly effective.

## CAVIES (GUINEA-PIGS).

**Description.**—Cavies or guinea-pigs (*Cavia porcellus*) are rodents, and are descended from one or more of the several kinds of wild cavy found in South America. They are believed to have been domesticated by the Incas long before Europeans "discovered" that part of the world. They make excellent pets, but are easily frightened, and should be treated gently and quietly. They usually behave quietly, although there may be fighting between adult males ("boars"), and the arrival of food—or the entry of a person into a room, which fact is obviously connected with feeding-time—usually sets up a chorus of chirruping squeaks. There is to-day a considerable cavy "fancy" in Great Britain and other countries, and many varieties are recognised, including rough-coated and smooth-coated types. Among recognised colours are the agouti (banded hairs), brindle, cinnamon, tortoiseshell (tricoloured), and Himalayan (white with attractive black points). The long-haired Peruvian and rosette-haired Abyssinian breeds are popular. Guinea-pigs may live up to two to three years. There is a small tail (composed of from five to seven caudal vertebrae), but usually this is so short that it does not project outside the body. There are four toes on each of the fore-feet and three on each hind foot. An adult guinea-pig may measure up to 10 in. or more in length, and sometimes its weight is well over 2 lb.

**Housing.**—Guinea-pigs may be kept outside or inside. If outside conditions are favoured, great care must be taken to protect them from dogs, cats, and rats. The last-named may be a danger also in conveying disease. The run should be in a sheltered position away from wind and direct summer sunlight. Tent-shaped waterproof shelters, with wooden floors covered by cleaning trays, have been found satisfactory. Another method is to keep them in hutches of the same type employed for rabbits and when conditions are suitable to let them out into a temporary run on the lawn surrounded by  $\frac{1}{2}$  in.-mesh wire-netting that is at least 12 in. high. (N.B. This will keep dogs or cats out.) Guinea-pigs will crop the grass and help to keep the lawn smooth. Great care should be taken not to allow the ground or floor to become so contaminated by guinea-pig excreta that it conveys disease from one animal to another.

If indoor methods are selected, an even, preferably warm temperature is desirable, and there should be freedom from draughts. Guinea-pigs have been found to thrive best at about 65° F. with a humidity range of 45–55 per cent. Provided warm conditions are available, metal cages are easier to keep clean than wooden ones, while a false bottom of wire mesh, above the cleaning tray, is helpful. Wood-wool is again the best bedding. Cages must not be too small, and a pair of pet guinea-pigs should have about 14 sq. ft. of floor space. It is a sound principle, as with rats and mice, to change frequently to a clean cage, the used one being cleaned and disinfected thoroughly before being used again.

**Feeding.**—Guinea-pigs, like human beings, apes, and monkeys, require a source of vitamin C (ascorbic acid). Normally they obtain this from greenfood, but in winter especially they may not secure enough in this way. The daily requirement of an adult guinea-pig is about 2 milligrammes, and supplies can be obtained from a chemist's shop.

There are many different methods of feeding guinea-pigs. Among cubed or pelleted diets is that known as "Diet 18," which is employed also for rabbits. It contains the following parts by weight: wheat feed, 15; grass meal, 30; decorated groundnut meal, 15; linseed cake, 10; barley meal, 20; common salt, 1; and chalk, 1. This is fed together with fresh greenfood to supply vitamin C. For feeding without the use of compressed diets a good plan is to provide a daily "concentrate ration" of about 1 oz. per head of a mixture of 2 parts bran and 1 part crushed oats, and to feed in addition ample amounts of cabbage, lettuce or other greenfood, meadow hay of good quality, grass, and raw vegetables. Although guinea-pigs normally derive moisture from fresh greenfood, and may

appear to take little or no water for long periods, it is a mistake not to provide a fresh supply, preferably from water bulbs, or from inverted bottles fitted with a stopper and drinking-spout. A little dried brewers' yeast makes an excellent addition to the diet, while for pregnant and lactating females ("sows") milk is excellent. Dead foliage should be removed from greenfood, and soil and dirt cleaned off. Frosted greenfood should be soaked in warm water before it is given to guinea-pigs. Unfortunately, hay may be contaminated by wild rodents, but it forms an excellent article of diet. Never allow food residues to remain in the cage.

**Breeding.**—The lactation period of the guinea-pig is a short one. The gestation period averages sixty-three to seventy-five days, although variations of fifty-eight to seventy-two days are known, and the young are born in an advanced state, with their eyes already open. They can run freely with their mother shortly after birth. They are able to nibble a little food as early as the second day, and by the time they are two to three weeks old they are completely independent and are neglected by their mother. A sow will often mate again the day the young are born, or shortly after, so that a rapid succession of litters often occurs.

Guinea-pigs are capable of mating from about fifty-five to seventy days of age, or even younger in certain circumstances, including the provision of a high plane of nutrition. The oestrous cycle averages fifteen to seventeen days, although it may vary from thirteen to twenty-five days. The actual period during which mating may occur usually lasts only from about six to eleven hours. One boar may run with as many as twenty sows if so desired, but in the case of pets it is much more interesting to run a boar with only one sow, in which case she need not usually be removed to a separate cage before the young are born. The young guinea-pigs should be separated from the older ones shortly after weaning, and the sexes separated at four to five weeks of age if they are not to breed prematurely. It is better to wait until the animals are approaching six months of age or so before they are mated, for they do not become fully grown and "filled out" until they are between six and nine months.

**Handling.**—Guinea-pigs are timid creatures, and should be handled gently. They are best picked up with both hands. If a guinea-pig is to be held in order to examine it for any purpose, a good method is to place one hand over the animal's shoulders, with the fingers and thumb around its neck, and to extend its hind limbs with the other hand.

**Diseases.**—The most important infectious disease of guinea-pigs is, like "mouse typhoid," caused by organisms of the *Salmonella* group, and it may be contracted from wild rodents or from food or bedding contaminated by them. In guinea-pigs the disease is known usually as "paratyphoid" (or sometimes as "salmonellosis"), and it may take an acute form, causing death within a few days, or a more chronic form in which many animals recover to become symptomless carriers of disease. Outwardly healthy, they may infect susceptible guinea-pigs with which they are placed. Cold or other environmental variations, and faulty feeding, can help to set off an outbreak, for there are few stocks in which the organisms are not lurking in some "latent carriers." *Coccidiosis* is common, but is a much less serious threat than in the case of rabbits. It has been set up in infected stocks by feeding inadequate diets, and provided that nutrition and hygiene are adequate there is rarely serious trouble from this disease. *Infections of the respiratory tract* may occur, but are uncommon except when there is overcrowding, high humidity, or damp bedding. Sometimes organisms of the *Pneumococcus* group cause not only disease of the respiratory tract but also a generalised infection of the serious membranes of the body. When this disease occurs it may produce death without much warning. It is possible that the infection sometimes comes from human beings. The disease known as *pseudotuberculosis*, and described under rabbits, occurs in guinea-pigs also. Again, environmental conditions and faulty feeding may predispose towards active infection.

With good fortune and sound management,

trouble from these serious infections may never occur. *External parasites* should be dealt with promptly by modern methods. Sometimes *non-parasitic skin disorders* occur when the diet is faulty, e.g., too dry or lacking in sufficient fresh greenfood of good quality.

## RABBITS.

**Description.**—Domesticated varieties of the wild European rabbit (*Oryctolagus cuniculus*) are now kept in many countries of the world. The wild rabbit is believed to have been introduced into Great Britain about the twelfth century A.D., and to-day it is a serious pest of agricultural land and forestry schemes. Tame rabbits have been bred for centuries, and some of the breeds and strains that have been produced differ appreciably in size, colour, and habits from the common wild form. Some breeds have been specially bred for table purposes, while others (e.g., the Angora, Sitka, and Argente de Champagne) have been developed for their fur. In addition, many varieties are produced for show purposes by the extensive rabbit "fancy." The small hardy Dutch rabbit (usually black and white) is one of the kinds suitable for beginners. Among well-known categories are the English, Japanese, Himalayan, Belgian Hare (really a rabbit), Flemish Giant, Beveren, Blue Imperial, Polish, Havana, Lop, Half-Lop, Chinchilla, and New Zealand White. The Copenhagen rabbit appears to be identical with the New Zealand White. The smaller breeds weigh only 4-6 lb. when fully grown, whereas some specimens of some of the giant breeds attain a weight of 20 lb. or more.

Rabbits and hares were formerly classified with the rodents, but to-day they are placed in a separate Order of mammals, known as the Lagomorphs. Young rabbits (in contrast to leverets or young hares) are blind and helpless for some time after birth. Tame specimens may live for four to five years, and individuals have lived for up to thirteen years.

Since rabbits are employed for commercial purposes, various systems of management have been devised, including the use of movable ark-huts, with covered runs, that can be moved regularly to fresh ground. If kept indoors rabbits do not need special heating, but freedom from draughts, damp, excessive cold, and access by wild rodents is most desirable. A garage is regarded as an unsuitable place, owing to the susceptibility of rabbits to exhaust or engine fumes. One of the great difficulties of rabbit-keeping is coccidiosis, which is a serious disease in rabbits and hares. (European hares could never be bred successfully in captivity until means of overcoming coccidiosis were discovered.) With young rabbits especially (i.e., those that have left the nest and are able to run about freely) it is a sound principle to move them to a clean floor or fresh ground every two days, so as to "break" the life-cycle of the coccidial parasite. One way of doing this is to have "back-to-back" cages or hutches, from one to the other of which the rabbits may be transferred easily. The empty cage or hutch may then be cleaned and disinfected thoroughly and allowed to dry out before the rabbits are returned to it. Wood-wool makes a suitable bedding material, although the female (doe) will pluck her own fur to line the nest when her litter is due to be born. Wire-mesh floors with a tray beneath are convenient, but if solid floors are used these should be sprinkled with fresh sawdust daily or every other day. Provided the standard of hygiene can be maintained, cages or hutches and their runs should be large. The absolute minimum is "1 sq. ft. of floor space for each 1 lb. weight of adult rabbit," i.e., if there are two rabbits totally 12 lb. in weight there must be at least 12 sq. ft. of floor space. If cages or hutches are stacked one on top of the other the lowest should be well clear of the ground, and if there is only one hutch this, for convenience and safety from wild rodents, should be 2-3 ft. off the floor.

**Feeding.**—The wild rabbit grazes at dusk and dawn, and it is preferable to feed tame rabbits twice daily, while pregnant or lactating does and young rabbits benefit from three meals a day. As in the case of guinea-pigs, the ration may be thought

of as consisting of two parts, a concentrate portion and a portion consisting of greenfood and other succulent material. The concentrate portion consists usually of a mixture of cereal grains or of some other form of mash. Successful mashes, of which there are many, include: (1) a mixture of 4 parts cereal grains and 1 part dairy cake; (2) equal parts of bran, weatings, flaked maize—or barley meal—and fish meal. This second is useful for breeding. If materials for the mash are in short supply they may in part be replaced by cooked potatoes. An average daily food allowance for a resting (non-breeding) adult of medium size would be: greenfood (grass, clover, weeds, lettuce, etc.) and/or roots, 12-16 oz.; hay (good quality), 2-3 oz.; and concentrates (cereal grain or meal mash), 2 oz. If cooked potatoes are used they should be fed at the rate of 4 parts to each 1 part of cereal that they replace. For a doe nursing her litter a suitable diet would comprise: greenfood to appetite, hay (good quality and preferably containing clover or other legume), 2-4 oz.; concentrates (preferably with fish meal or some other suitable source of "animal protein"), 4-6 oz.; and common salt at the level of up to 1 per cent. of the ration. A mineral mixture is preferable to salt alone. Excessive greenfood, especially in the form of cabbage and other Brassica plants, may cause polyuria, i.e., the passage of excessive quantities of urine. No matter how much fresh greenfood rabbits may have available, a supply of fresh water should always be provided. The daily water requirement of the rabbit is quite high, and certain bad habits such as urine drinking or even cannibalism may result from an inadequate intake of water. Pots that cannot be overturned or, preferably, water bulbs or bottles as described for guinea-pigs, are the most suitable means of providing water.

"Diet 18," described under guinea-pigs, is one of several types of compressed diet successfully employed for rabbits. Fresh greenfood is preferably fed in addition, while the water requirement with diets of this kind is considerable.

**Breeding.**—The age of puberty varies with the breed, and also with the time of year at which the individual rabbit was born. Rabbits born in spring are usually capable of breeding at a younger age than those born in the autumn. In Great Britain the wild rabbit has a fairly sharply defined main breeding season, lasting from January to June, but some degree of "out-of-season" breeding may take place at almost all other times. Tame rabbits may not breed freely during the winter months, especially if environmental conditions are cold. Mating may take place as early as four months of age, and although this does not often result in pregnancy, it is accompanied by competition and fighting between individuals of the same sex. Males (bucks) and females should therefore be separated at weaning, or at least before they are four months old. Fertile matings may occur at from about 5½ months of age onwards, but it is wise to defer breeding until later—say seven to eight months for most breeds. The female does not ovulate or shed her eggs from the ovary spontaneously as do most domestic mammals, but, like the cat and ferret, does so in response to the act of mating or some other strong stimulus. Even playing between two does may precipitate ovulation, in which case a so-called "phantom pregnancy" (pseudopregnancy) may result, the doe that has ovulated appearing pregnant and even developing lactating mammary glands. There is not therefore an obvious regularly recurring oestrus cycle as in the domestic rat, mouse, and guinea-pig, and in summer at least the doe may be ready to mate at almost any time. Observation suggests, however, that there are fluctuations in the desire to mate. The act of mating in rabbits sometimes causes alarm that all is not well to those that have not hitherto witnessed it, for the buck usually emits a peculiar cry and loses his balance to fall over sideways. It is usually best to separate the buck from the doe before the young are born. The gestation period is usually thirty to thirty-two days. In wild rabbits a high percentage of embryos die and are "resorbed," and are therefore never born. In some populations it appears that about two-thirds of all rabbits conceived (including about 60 per cent. of total litters) are lost before birth in this way. Losses from this cause are probably

much less common in domesticated rabbits, especially when the standards of feeding and management are high. Litter size is variable, and depends in part on the breed or strain. In some strains mean litter sizes up to eight or nine have been obtained, but a mean of four or so is more common. Does that do not prepare the nest or rear their young properly should not be selected for further breeding. The doe with her new-born litter should not be disturbed unduly, or she may desert her young, which are blind and helpless at birth and are entirely dependent on her for at least three weeks, after which they begin to nibble food to supplement the milk that they receive from her. The eyes open at about fourteen days. Weaning should be carried out at between six and eight weeks of age, by which time the young should be able to fend for themselves completely.

**Handling.**—Rabbits should never be lifted by the ears alone. One good way of lifting them is to grip the ears firmly but gently with one hand and to place the other hand under the rump to take the weight of the rabbit's body. Alternatively, one hand may be placed flat under the rabbit's belly, but this requires more care, and may be a risky procedure with pregnant does. Another convenient way to handle rabbits, especially young ones, is to lift them by the loose skin over the shoulders. Rabbits can inflict quite nasty scratches with the nails of the hind feet. It is incidentally a good plan to examine the nails of all four feet and to trim them if they are too long. A stout pair of scissors, or preferably a pair of clippers, is used, and care should be taken not to cut back as far as the "quick," i.e., the bluish portion at the base of the nail that contains blood vessels and will bleed freely if damaged.

**Diseases.**—As already indicated, *coccidiosis* is a highly important disease of young rabbits. It may be either of the "hepatic type," affecting principally the liver, or the "intestinal type," affecting principally the gut. Even in the case of the hepatic type, however, the coccidial parasites are picked up by mouth and after penetrating the intestinal walls make their way via the blood-stream to the liver. Hygienic measures are the best means of preventing the disease (see under Housing), but should it break out, prompt treatment with certain sulphonamides or other anti-coccidial drugs may prove effective. In certain rabbitries in which coccidiosis is a constant problem, protection has been obtained by feeding a dilute solution of one of the soluble sulphonamides in place of drinking-water. There are certain types of digestive disturbance that may resemble coccidiosis, and one of these, the cause of which has not yet been established with certainty, is known as *mucoid enteritis*. Some such cases are probably variations of "bloat" ("the blows"), a condition the cause of which is again not fully established, although there may in fact be several factors. A rabbit may, of course, "bloat" after eating fermentative food, but cases of "bloat" can occur independently of this, and some may be due to a virus. "Snuffles" is characterised by a nasal discharge, and is not always associated with the same organism. In its milder forms it is not a severe disease, but with the more chronic forms the nasal discharge becomes marked and gives rise to a typical snuffing noise. Severe chronic cases become progressively worse and die of a terminal pneumonia. There is also a severe acute form, in which the rabbit dies so rapidly that the condition is sometimes not recognised. Acute cases that are treated in time with certain sulphonamides may respond well, but chronic snuffles are difficult to treat and go on spreading the infection, and hence are better destroyed. Correct environmental conditions are a great help in preventing this disease. A chronic type of infection is known as *pseudotuberculosis*, which is usually acquired from eating material contaminated by wild rodents or by other infected rabbits. It is caused by quite a different organism from that of true tuberculosis, which is much rarer in rabbits. Clinical cases should be killed, and prevention lies in hygienic measures. Infected wounds or skin abscesses may lead to a disease caused by the "necrosis bacillus" (*Fusiformis necrophorus*) and known sometimes as *necrobacillosis*. It is usually characterised by

subcutaneous swellings distributed irregularly over the head and body. Although in the early stages the affected rabbit may remain in apparently good health, the spread of the disease is insidious and usually fatal, and in most instances it is kinder and safer to destroy a case before it progresses too far. There are unfortunately several other infectious conditions occurring in rabbits, but all call for expert help in diagnosis and treatment. Generally speaking, it is a bad policy not to cull an ailing rabbit immediately, and one that is ill should certainly be isolated at once and not fed or tended before the person looking after it touches the healthy rabbits.

Among non-infectious conditions *pregnancy toxemia* is not uncommon in does during the very late pregnancy, and usually proves fatal within two to three days. It is a "metabolic disorder," i.e., it is associated with some functional derangement of the endocrine or ductless glands or with the inability to control properly the utilisation of its food. Faulty feeding is probably a contributory cause. Diseases of the heart and blood may arise occasionally, and can be aggravated by faulty feeding.

Among external parasites, *ringworm* is not common, but may be acquired from rodents. Affected rabbits that are to be treated must be isolated. *Ear mange* (known usually as *ear canker*) is common, and may be treated by strict attention to hygiene, with thorough disinfection of the hut or cage, and by dressing with a modern anti-mange preparation. *Body mange* is much less common but far more difficult to treat.

Among internal parasites, so-called "*bladder worms*," i.e., the larval stages of two dog tapeworms (*Taenia pisiformis* and *Taenia serialis*) are quite common, although rarely fatal. The feeding of grass or other greenstuff to which dogs have had access should be avoided, as well as the contamination of the drinking-water with dog faeces.

Domestic rabbits are susceptible to myxomatosis (See "General Information," p. 648), and it is a wise precaution to have them vaccinated. The vaccine is inexpensive, and may be obtained through veterinary surgeons and pharmacists.

## HEDGEHOGS.

**Description.**—The European hedgehog (*Erinaceus europaeus*), found throughout Great Britain, belongs to the Order Insectivora, of which moles and shrews are also members. Its diet is, however, by no means restricted to insects, although in nature a considerable portion is probably made up of small invertebrates. There is a good deal of prejudice against them as pets, owing to the fact that freshly caught specimens are usually infested with fleas or other external parasites. The spines of the hedgehog, being well-spaced, make the presence of external parasites more obvious than is the case in animals with a coat of close fur. The hedgehog's spines form its defence, and its capacity to roll up into a prickly ball at the threat of danger is well known. This defence reaction is unfortunately of no avail to it when the danger is an oncoming car or lorry, and thousands of hedgehogs die every year as a result of being killed by vehicles on the roads. Many other species of mammals wander on to the roads, but most attempt to flee when they sense the approach of a vehicle. The capacity to roll up is not secure defence even against animal enemies. There are some foxes, dogs, and cats that have learned to "uncurl" a hedgehog, and subsequently eat it.

Provided that care is taken, a hedgehog makes an excellent pet, especially if given a suitable enclosure in the garden. For a variable time during winter hedgehogs hibernate, and during this time they must not be disturbed. Should they emerge at any time, however, food must be provided. Some specimens have lived for five years or more in captivity.

**Accommodation.**—The most satisfactory way to maintain a pet hedgehog is to provide it with a large "run" in part of the garden. If wire-netting is employed it should be sunk under the ground to a depth of several inches, or the hedgehog will burrow underneath and escape. The top of the run must be wired in, or alternatively

there must be a "baffle board" or wire-frame (at least 9 in. wide) near the top of the sides to prevent escape that way, for hedgehogs can scale wire-netting—and some other types of fence—with ease. There should be a warm, dry box for shelter, containing wood-wool or other bedding material. A simple but suitable shelter may be made out of a soap-box, preferably lined with asbestos sheeting or some other material impervious to water. A shallow sunken bath in the enclosure may be of interest, for hedgehogs take well to water, but the edges should be such that the hedgehog can get out easily.

If it is decided to keep a hedgehog indoors, then the best accommodation is probably similar to that described for ferrets.

**Feeding.**—The simplest diet consists of milk, some bread, and minced lean meat. Cooked meat is preferred to raw, but raw liver should be given occasionally. Another satisfactory diet comprises meat offals, "root" vegetables (e.g., carrot, potato, and swede), and wheaten wholemeal biscuit, steamed together until cooked, and then mixed and minced with a small proportion of raw liver. A small quantity (say 1-2 per cent.) of mineral mixture is also desirable, and milk should be given freely. Although hedgehogs appear to drink but little water, a fresh supply should always be provided.

**Breeding.**—During the breeding season marked changes occur in both males and females, and the structures associated with reproduction increase enormously in size from about March onwards. The female is capable of having two litters a year, the first in May or June and the second in August or September. The period of gestation has not been determined exactly, but is believed to be thirty-five days, possibly with variations of up to well over forty days. During the breeding season the males are very pugnacious towards each other if females are with them, and may do each other considerable damage. (The mixing of strange hedgehogs is often a difficult procedure anyway, for they often fight and inflict nasty bites on one another's feet.)

The litter size is usually four to six, and the young, which have "soft" spines, are suckled by their mother for nearly six weeks. The young can partake of some solid food at about three weeks, and there is some evidence that if left with their mother for longer than six weeks she may compete unfairly with them for food!

**Diseases.**—Hedgehogs in captivity are susceptible to *respiratory infections*, and can sometimes contract certain strains of *human influenza*. They are susceptible also to *Salmonellosis* (see under mice and guinea-pigs). Fleas and other external parasites have been mentioned; these often disappear spontaneously as the hedgehog begins to thrive in captivity, but if not they should be dealt with by modern methods.

## LAND TORTOISES.

Tortoises are popular pets, but although many are kept with great success in Great Britain, the majority of those that are imported each year are never looked after adequately, or fail to thrive for other reasons.

Most land tortoises that are imported into Great Britain for sale through the dealers are: (1) the Spur-thighed Mediterranean Land Tortoise (*Testudo graeca*), commonly known as the "Moroccan tortoise" and sometimes as the "Iberian" or "Algerian"; or (2) Hermann's Tortoise (*Testudo hermanni*). The second is distributed in Southern France, Southern Italy, the larger islands of the Western Mediterranean, and parts of Yugoslavia, Albania, and Greece. There is a species found in Greece, the Margined Tortoise (*Testudo marginata*), but while adaptable to life in Great Britain, it is more difficult to acquire. The two common species differ in several ways, the "Moroccan tortoise" having a small bony spur on the back of the thigh. (The upper part of the shell is termed the carapace and the ventral portion the plastron.)

In selecting a tortoise one should ensure that the animal appears healthy. It should be active and withdraw quickly into its shell on being dis-

turbed. Its legs should be firm and not limp, and there should be no abnormal discharge from the eyes or nostrils. The shell and limbs should be uninjured. Females are generally larger and have a shorter tail than the male. The shield above the tail is flat in the former and curved in the male. It is a good idea to obtain a pair or more of tortoises, but not more than can be looked after with care. On being purchased they should be washed in tepid water.

Many tortoises are given free range in gardens, but this is not advised with all, as they eat a wide variety of vegetables and young plants, and being wandering animals are liable to get lost if the garden is not completely fenced or walled. They should be provided with as large a "pen" or "run" as possible, the walls or wire netting of which should be high enough to prevent their climbing over. The practice of tethering tortoises by a hole in the shell should be discouraged. They should always be provided with a box or shelter, the cheapest form being a wooden soap box turned on one side and with a sufficiently wide entrance, the wood being creosoted and covered with roofing felt. It can be lined with asbestos sheeting if desired, and have its floor covered with dry leaves or other bedding material. Some other shelter should also be provided in the run. The tortoises should be bathed during the hot weather. The occasional application of olive oil will keep the shell polished.

Land tortoises must be fed daily, and it is important to allow them to build up good reserves to enable them to hibernate through the winter successfully. Suitable foods include lettuce, young cabbage, peas, clover, dandelions, and a wide variety of green plants and ripe, sweet fruits. Generally bread and milk should be avoided. For young tortoises especially, it is recommended that once weekly or so the food should be sprinkled with powdered cuttlefish bone, or better still a small quantity of powdered calcium gluconate or cod-liver oil. Fresh water in a shallow tray, or even a saucer, should always be provided.

One of the most difficult problems in tortoise keeping is hibernation. Some persons avoid allowing their pets to hibernate by transferring them to a warm place, such as a heated greenhouse; if this is done they must be kept well fed and their place maintained at a summer temperature. It is imperative to do one thing or the other—the half-torpid tortoise that is neither hibernating nor kept at summer temperature will die. Moreover, a tortoise that is allowed to hibernate must not be disturbed.

Signs of pending hibernation, including sluggishness and lowered appetite, are usually evident late in September or early in October. Tortoises living in the garden may commence to bury themselves. If this is allowed they must be well covered, else they may be killed by the ensuing frost. It is, though, more convenient and perhaps provides a greater chance of survival, due to the changeable winter conditions in Britain, to place the animal in a large box, which should be packed with straw, leaves, or hay. The box should be stored in a cool but frostproof place, such as out-building, cellar, or attic. It is important not to create conditions that will awaken the tortoise or tempt it to emerge before the following spring. Rats have been known to attack hibernating tortoises, and so due precautions should be taken.

On emerging from hibernation the eyes and nostrils are somewhat sealed, and should be released by bathing with a 4 per cent. boric acid solution and warm water.

Recently imported female tortoises frequently lay eggs, but it is not a common occurrence for pairs to breed freely in Britain. During the early part of the summer the male is sometimes seen butting the shell of the female, this being a courtship action. If eggs are laid it is unlikely that they will be fertile, and less likely that they can be hatched. They have been hatched by placing them on damp sand and storing them in a warm place—a heated greenhouse or airing cupboard. The eggs should not be disturbed or "turned" once incubation has commenced.

Tortoise ticks are often present on freshly imported specimens, and may best be removed by damping the tick first with paraffin or methylated spirits and then removing it gently with tweezers. Round worms are very numerous in tortoises, and

should they be seen in the faecal matter the remainder may be best eliminated by sprinkling up to one grain of powdered santonin on the food once a week for six weeks. Eye infections are common, and are usually remedied by bathing the eye well with a 4 per cent. boric acid solution or warm cod-liver oil. Continuous discharge from the nose indicates lung infection, and as a primary measure the animal should be kept warm. Bleeding can be stopped by using Friar's Balsam, and care should be taken to prevent insects settling on open wounds.

## WATER TORTOISES (TERRAPINS).

In Great Britain the tortoises that have become adapted to life in ponds and rivers are usually termed "terrapins," the name turtle being applied to marine forms. In the U.S.A. and Canada, however, not only the marine species but also terrapins and tortoises are all termed "turtles."

Several kinds of terrapin are available and capable of thriving in Great Britain. These include several American species, the European Pond Tortoise (*Emys orbicularis*), the Spanish Terrapin (*Emys lepida*), the Caspian Terrapin (*Emys caspica*), and the Reeves' Terrapin (*Chinemys reevesii*), which hails from China and Japan.

The ideal place in which to keep terrapins is a garden pond within an enclosure. The pond should contain an "island" of dry ground on to which the animals can climb easily. The water should vary in depth, and at one point be at least 2 ft. deep. Provided that there is a suitable "island" the boundary walls of the pond can be upright to prevent escape. The final coat of cement should be smooth and mixed with a waterproofing agent. Shade should be available, not only on the island but also in some parts of the water. This may be provided by suitable plants.

Terrapins are almost entirely carnivorous, although the young of some species may take a little lettuce or other vegetable food. Suitable foods include small pieces of raw meat, raw liver (this should certainly be given from time to time), fish, and earthworms. Terrapins prefer to take their food in the water, and it is best to feed them individually if there are several, to ensure that each receives his proper share.

Water tortoises also hibernate. Some bury themselves in mud or sand at the bottom of their ponds, others will dig themselves into the earth in the island or banks of their pond, while others again may go to sleep in the box that, as in the case of land tortoises, should preferably be provided for them on part of their "land." Should they sleep at the bottom of the pond, it is as well to prevent freezing of the water. One means of doing this is to leave a log or logs floating on the surface. Moving these logs on cold mornings will help to break any ice formed and to prevent total freezing.

## AQUARIUM FISH.

There are two types of aquaria—the cold-water, for fish from this and other temperate countries, and the heated, for tropical varieties of fish. Apart from the fact that a suitable heating mechanism—usually electric, with thermostat control—has to be maintained for tropical aquaria, the general principles governing the two types are much the same. There is a certain amount of additional initial expense in setting up a heated aquarium—the running costs are not high—but in some respects tropical fish are easier to maintain than many of the cold-water varieties.

It should be emphasised at the outset that those who want to keep fish should invest in a proper aquarium and not in a "goldfish bowl," unless the latter be very large in relation to the fish to be kept. Far too many fish suffer from overcrowding or from lack of sufficient water surface. In the case of cold-water fish, it has

been calculated that every "1 in. of body" requires 1 sq. ft. of water surface in order to obtain sufficient oxygen for respiration. Thus a fish the body of which (i.e., the length minus the tail fins) is 4 in. will require at least 4 sq. ft. of water surface, i.e., an area of 2 ft. × 2 ft. Two such fish will require twice this area, and so on. In *The Right Way to Keep Pet Fish* by R. Dutta (6s.), it is pointed out that a goldfish should normally live for twenty-five years in a suitable pond, and grow to its full length of over 14 in. There are few indoor aquaria capable of supporting many full-grown goldfish in adequate conditions, and indeed it is recommended that fish such as shubunkins, fantails, veiltails, and orandas, which grow more slowly, are far better adapted to cold-water aquaria than goldfish. Tropical fish of the varieties kept in aquaria are usually much smaller. Many have an average body length of only about 1½ in., and eighteen such fish may be maintained in a suitably heated tank with an area of water surface of 18 in. × 12 in.

A beginner should not only read good books on the subject (including *Water Life* publications) but also consult experts and his local aquarist or dealer. Whatever aquarium is chosen, the conditions should be correct before any fish are introduced. Should fish be suddenly acquired, before a proper aquarium has been fitted up for them, they should be kept in some temporary (but sufficiently capacious) quarters until the aquarium is ready.

The instructions for installing and fitting up an aquarium are usually supplied, and should be followed carefully. The sand that is usually placed on the bottom should be thoroughly washed, and is best put in a little at a time. Make sure that the inside of the aquarium is thoroughly clean before anything at all is put into it. Ornamental rocks may next be introduced, and great care should be taken to ensure that these are of the correct type, unlikely to harm the fish physically or chemically. Water is then added very gently indeed, and suitable plants set. In the case of large tanks the planting is best done when the tank is only partly filled with water, but in any event the plants themselves should be kept wet all the time, or they may quickly shrivel up. In the case of cold-water aquaria everything may now be left for a few days—preferably a week or more—to ensure that all is well, and to allow certain micro-organisms that help form the food of the fish to develop. In the case of heated aquaria it is necessary also to ensure that the thermostat is working correctly and that the temperature is remaining constant or within very narrow limits. Here again it is advisable to wait at least a week before introducing any fish. Should conditions "go wrong" before or after the fish are introduced, it is best to start filling the tank all over again.

Fish should not be overfed, although regular feeding is essential. Attention must be paid to the feeding instructions issued with prepared fish foods, and to details given by the supplier of "live" foods. Provided fish are neither overcrowded nor overfed, the amount of sediment that accumulates in the tank will not be excessive, but it should be siphoned away gently every month, or more often if necessary. Water lost by evaporation should be replaced, and in the case of heated tanks especially, it is most desirable that the added water be of the same temperature as that already in the tank.

Certain species of water snail are often placed in aquaria to act as scavengers. It is necessary to ensure that, if snails are kept, they are of the right type, and it is important to consult experts on this matter.

Breeding is an interesting topic, there being both egg-laying and viviparous or "live-bearing" fish. The beginner is well advised to learn first how to keep fish in healthy condition in his aquarium before indulging in any planned breeding, and he should study the relevant information in books on the subject.

An aeration plant is often recommended on the grounds that it will increase the fish-carrying capacity of the aquarium. This is true up to a point, but overcrowding may bring other troubles besides those connected with lack of sufficient oxygen, and the golden rule is never to keep too many fish for the size of aquarium in question.

Another factor to be remembered is that should the aerator break down it may leave the fish with less oxygen than their proper requirement. It has been recommended that an aerator is best thought of as a stand-by, to be employed only in emergencies, *e.g.*, when for some reason extra fish have to be added to a tank already holding all or almost all its proper capacity.

There are unfortunately many diseases of fish, and as yet scientific knowledge concerning many of them is far less detailed than it should be. It is clear, however, that environmental factors are responsible for many deaths or cases of unthriftiness, and among the factors concerned may be listed: overcrowding, overfeeding, the provision of a diet that is qualitatively inadequate, lack of "balance" in the aquarium leading to unsuitable conditions, dirt, too strong light, lead paint and noxious substances, that may somehow have come into contact with the water (*e.g.*, from the hands of the person tending them) or been absorbed from the atmosphere. One must be careful of such things as disinfectants, soaps, petrol, etc. In the case of tropical fish the temperature of the water may be incorrect. Should fish troubles occur, therefore, it is as well to consider these various possibilities, although one should not hesitate to seek professional advice where there appears to be a case of infectious disease. An illing fish should certainly be removed from the tank (assuming that there are other fish present) and given separate quarters of its own if such a course is feasible.

It is not intended to provide a description of the separate diseases, although it may be mentioned that such signs as the appearance of material resembling cotton-wool (actual fungal growths) and "rotting" of the tail or fins, are among those that should lead the owner to isolate affected fish and to seek help immediately.

No attempt is made here to describe any of the many different species and varieties of fish suitable for private aquaria. Some of the "points"

of a fish are shown in the accompanying illustration. Great care must be taken in mixing species, *e.g.*, "hard mouthed" and "soft mouthed" kinds should not be kept together. The temptation to put other species (*e.g.*, newts) with aquarium fish must likewise be avoided.

### CAGE BIRDS.

Very many species and varieties of birds are now maintained successfully in captivity, and there exists in Great Britain a large and expanding "cage-bird fancy," that caters for a considerable proportion of the smaller birds adapted to cage or aviary life.

The different types and sizes of birds have different requirements, and in the space available it is not possible to do more than cover the general principles and to deal briefly with the special characteristics of the management of the more easily maintained species. The beginner is advised to restrict his attention to one of the better-known species, *e.g.*, canaries or budgerigars, and not to attempt to maintain exotic varieties until he has acquired considerable experience.

Most species thrive best in aviaries, which may be indoor, outdoor, or of the combined "outdoor-indoor" type. An indoor aviary is usually all-wire and portable. The criticism of many such aviaries is that they tend to be high and narrow, whereas a fairly large floor-space is desirable.

They should not be placed in cold or draughty places, nor too near a fire. If sited so as to receive much direct sunlight they must have adequate shelter. The wires must be close together, especially if smaller species are kept, a distance between them of about  $\frac{1}{4}$  in. being generally suitable. An outdoor aviary—suitable only for some species or at certain times in the case of others—should occupy a sunny position, although it too must include shade, and must be protected from winds. There ought in fact to be a sheltered portion, dry and well protected from the elements. The aviary must be strongly made and safe from all predators, including rats. While it is often considered desirable to allow herbage to protrude through the wire-mesh floor, it is essential that the birds are never in close contact with wild rodents or their droppings. Most birds are highly susceptible to some forms of *salmonellosis* (see under mice and guinea-pigs), and can contract them in this way. It is advisable also that the roof of the aviary is solid: corrugated asbestos sheeting, projected well clear of the edges of the uprights so as to prevent water and other matter from entering the interior, is excellent. The droppings of wild birds may be a potent source of bacterial infection or of internal parasites. To prevent close contact otherwise with wild birds, the wire or wire-netting "walls" of the aviary may be double. If an "outdoor-indoor" aviary is employed, there is usually an indoor flight cage, separated from the external portion either by a very light hanging door of suitable size, through which the birds can easily push their way, or by a sliding partition that the owner can operate as required.

If an aviary is out of the question, then a suitable cage should be purchased or constructed. The cage need not be ornate—indeed simplicity of design usually facilitates the highly important task of keeping everything clean—but it must be large enough. A cross-section through a breeding-cage suitable for canaries, and for many other species, is shown in the accompanying illustration. Such a cage should measure about 40 in. in length  $\times$  12 in. wide  $\times$  18 in. high. It is constructed of wood or some suitable sheeting except for the front, which consists of vertical wires with horizontal stays, and can be divided into two parts by means of a suitable partition containing a removable section made of wire. By this means the cock and hen canaries can be introduced into the separate sections and develop a courtship before being allowed to be together for actual mating. The cross-section indicates the site and size of the removable portion of the partition, and it shows also the removable tray that is such an excellent fitting for almost any type of cage, and which greatly facilitates cleaning.

SECTION THROUGH CAGE.

Whether an aviary or a cage is employed, it is essential to have proper fittings, including conveniently placed drinking-troughs, feeding-trays and bird-baths, and good perches. Much unnecessary discomfort is brought about through the use of unsuitable perches, or ones that are incorrectly situated or not sufficiently "firm."

A suitable type of perch, of which there should be several in the cage or aviary, is shown in the accompanying illustration, and it should be of the appropriate dimensions for the size of bird. In the case of the larger canaries (Norwich and

PERCH.

Yorkshire), e.g., the sectional measurements should be  $\frac{3}{4}$  in.  $\times$   $\frac{1}{2}$  in., whereas for a smaller canary (Border) they should be  $\frac{1}{2}$  in.  $\times$   $\frac{1}{4}$  in. The type of perch shown is easy to clean and does not possess awkward corners in which parasites may be harboured. The dimensions of a nesting-

NESTING-BOX WITH PLAIN WOOD BOTTOM.

box, a bird-bath, and a feeding-tray suitable for canaries are also given in the accompanying illustrations.

While wood is a convenient material for aviary and cage construction, it has, of course, several disadvantages. Out of doors it is best creosoted

BIRD BATH.

(lead paints must never be used for places in which birds or other small animals are kept), and indoors it is better lined with hard asbestos sheeting. Metal is suitable—provided that it does not rust or corrode and that the environmental conditions are warm enough.

In all cases a supply of clean, fresh water should be available. Strict cleanliness should be observed, and professional advice taken immediately if a bird is not thriving.

SEED TROUGH.

**CANARIES** (*Serinus canarius*).—These are domesticated forms of the race of wild serin found in the Canary Islands, and may live up to twenty-five years. Many varieties are known, and although most individuals are "canary yellow," other colours have been developed by fanciers. Many books have been written about the canary, although there is still much to be learned concerning its feeding and diseases—as is indeed the case with almost all cage-birds. The system of feeding generally recommended is based upon a mixture of 2 or 3 parts of canary seed (which is rich in energy, and which is sometimes mixed with a little millet seed) to 1 part of summer rape seed, which is high in fat and protein. There seems to have been some difficulty in obtaining suitable rape seed in some areas since the war. The best is German summer rape or Rübsen rape. Other seeds are employed as substitutes, or for special purposes, e.g., niger is usually added at breeding time, and linseed if there is any indication of premature or soft (out-of-season) moult. A little greenfood should be provided twice weekly, and a piece of cuttlefish bone placed between the wires is a suitable source of calcium. Soft-bill food (containing boiled egg, dried egg yolk, dried flies, and ants' pupae) is also recommended by many breeders, while others give chopped egg alone. Others again favour milk, especially for young birds.

Breeding is usually started late in March or early in April, but not unless the daily shade temperature is at least 50° F. The pairs should be selected earlier than this and transferred to breeding-cages, with the partition in position. By the middle of February the wire partition may be installed so that the two birds can see one another. A little niger seed is usually added to the diet, while finely ground oystershell or eggshell may be sprinkled on the floor. (Otherwise the floor may be covered with washed sand that is not too fine and is free from dust.) When the birds begin to feed one another through the wire they are ready for mating, and the partition may be removed. The nest-box can then be inserted and suitable nesting materials, e.g., cow hair and moss, placed in the cage. The incubation period is thirteen to fourteen days. After the eggs are laid it is customary to separate the cock and the hen again, but to allow him to rejoin her after the young are all about eight to nine days old and have opened their eyes. If it is desired that all the chicks be hatched together, then one can remove the first three eggs that are laid—usually one egg is laid daily—and keep them in a box at room temperature, substituting dummy eggs for them in the nest-box. On the afternoon of the third day of laying they are returned to the nest-box in place of the dummies.

When the young chicks are able to feed for themselves they should be provided with special food, such as egg and bread crumbs and a little cracked canary seed. If the cock bird interferes with them, or causes the hen to neglect them, he must be returned to his own section. Usually, however, all goes well, and the hen will go to the nest again when the first chicks are almost sixteen days old. Some three or four broods may be raised in a season.

**WEAVER BIRDS.** In all the more tropical parts of the Old World and Australia there are found one or more kinds of weaver bird—so-called because of the complicated type of nest that is "woven" out of suitable material. Many species have been adapted successfully to captivity. The

term "weaver birds" is somewhat loosely applied to more than one group of birds. So far as aviculturists are concerned, African Weavers or Weaving Finches are grouped apart from other birds. They vary in size from that of a Tit to that of a Starling, and belong to the very large Ploceidae family. African Weavers include:

(a) Viduline Weavers (genus *Pyromelana*), which are the prettiest and are closely related to the Whydahs. Among them are the *Orange*, *Crimson-crowned*, *Black-bellied*, *Grenadier*, *Napoleon*, *Taha*, *Yellow-backed*, *Red-billed*, *Russ's*, *Red-headed*, *Mahali*, and certain others which are not often imported into Great Britain.

(b) Poiceine Weavers, among them the *Abyssinian*, *Rufous-necked*, *Spotted-backed*, *Cabanis*, *Black-headed*, *Black-fronted*, *Half-masked*, *Golden*, *Little-masked*, *Harilaubs*, *Madagascar*, *Yellow*, *Scaly-crowned*, *Blue-billed*, *Thick-billed*, *Dinemellis*, and *Buffalo*.

Closely related are the Indian Weavers, of which there are four species recognised aviculturally. Only one of these, the *Bayo*, is normally imported into Great Britain. The *Java weaver* and the *Nelicourvi* (from Madagascar) are also closely related. All these weaving birds are grain-eaters, and in captivity their staple diet is millet seed. When housed with insectivorous birds, however, they often sample soft food. The basic treatment is on the whole similar to that of canaries, although the male and female are usually left together at all times, and that special provision may have to be made for nest-building in those species that breed well in captivity. For individual details the reader should consult *Animals as Pets* by Margaret Ward and James Fisher (16s.), which is a mine of information on pet animals in general. *Foreign Birds for Beginners* by D. H. S. Risdon (10s. 6d.) and *Foreign Birds for Garden Aviaries* by Alec Brooksbank (10s. 6d.) are also excellent sources of reference for those interested in these and other species of foreign birds.

**BUDGERIGARS.** The Budgerigar (*Melopsittacus undulatus*) has been bred seriously in captivity only during the past half-century or so, and yet it already has a large "fancy" and a wide range of colour varieties, e.g., greens, blues, whites, yellow, grey-wings, cinnamon-wings, greys, and a "slate." All are domesticated forms of the wild budgerigar, which is green, with yellow head, blue on the face, wings and tail, and grey streaks. The wild budgerigar belongs to the parrot family, but is a small social bird that is found in the grasslands of Australia.

Adult budgerigars show a fairly wide range of body weight, variations being of the order of 18 to over 40 gm., i.e., from just over  $\frac{1}{2}$  oz. to about  $1\frac{1}{2}$  oz. Males may be distinguished by the fact that the "cere" or skin covering the base of the beak is blue, whereas in females it is brown.

Budgerigars are normally sociable birds, and should be kept in pairs or groups unless one intends to teach an individual (which should be a male) to talk, in which case it has to be kept alone. While "outdoor-indoor" aviaries are best, they will thrive in cages of adequate size, and that suggested for canaries, but without the partition, is suitable for one pair. For breeding purposes a covered nest-box is desirable, but while budgerigars will breed all the year round, it is preferable to take the nesting-boxes down in Autumn and not to put them up again until the following April. The incubation period averages eighteen days, but begins when the first egg is laid, so that the young are of different ages. The first will leave the nest at about four weeks of age.

The feeding of budgerigars may be based on a mixture containing approximately equal parts of canary seed and millet. Flowering grass, chickweed, lettuce, or spray millet should be given in addition, and it is a good idea to place a grass turf in the aviary. On the average, a budgerigar will consume about an eggcupful of seed daily. More

food is usually taken by birds which can take ample exercise in outside flights. A cuttlefish bone should be placed between the wires, and fresh water provided at all times.

Budgerigars may contract many of the bird diseases, and it is wise to seek professional advice at once should a bird seem off colour. One particular form of disease found in captive budgerigars is so-called "French moult," which usually afflicts young birds that are beginning to fledge, and prevents their flying, hence the term "runners." Although some authorities believe the trouble to be due to a mite, there is still controversy over its exact cause. In any event, however, standards of feeding should be high, and every attempt made to deal with external parasites.

An authoritative work on many aspects of the subject is *The Cult of the Budgerigar* by W. Watmough (21s.).

**PARROTS, PARRAKEETS, LOVEBIRDS, PARROTLETS, AND COCKATOOS.** Parrots and parakeets (the name given to small varieties of parrot, usually with long tails) are found in all the tropical regions of the world, and many have been kept successfully in captivity. Lovebirds (species of *Agapornis*, from Africa) and parrotlets (such as the Guiana Parrotlet, *Forpus passerinus*, from Central and South America) are small birds well suited to captivity and becoming more popular in Great Britain as the recent work *Lovebirds and Parrotlets* by L. P. Luke (8s. 6d.) indicates. Cockatoos are found wild in Australia, and several types (including species of *Kakatoe* and also the Cockatiel (*Leptolophus hollandicus*)) do well in captivity.

Several years prior to the last war a ban was imposed on the importation of parrots. This was on account of the fact that they were often found to be infected with a virus disease, termed "psittacosis," that was infectious for human beings, in which it caused a severe pneumonia. It has since been discovered that psittacosis, known popularly as "parrot disease," is by no means confined to the parrot family, but may occur in various other species, including some sea-birds and also pigeons. It has indeed been found in stocks of pigeons in the U.S.A. and in Great Britain. The name "ornithosis" is now often used in place of psittacosis, while the ban on parrots has been lifted.

Parrots are mainly birds of the forest, and in the wild make nests in holes in trees.

Aviaries of the outdoor-indoor type are suitable for most parrots, but they all need sufficient warmth, and must not be exposed to draughts or cold. Some form of heating may be desirable in colder weather. (Many parrot ills seem to respond to keeping the bird at quite a high environmental temperature.) If a cage is employed it should be of sufficient size. It is best to cover the cage at night with a dark cloth or open covering which should, however, be cleaned regularly and not serve as a reservoir of dirt or infection.

For all the larger parrots the basal diet found to be satisfactory in Zoological Gardens and elsewhere comprises hemp, sunflower seed, canary seed, oats, and apple. This is supplemented in various ways for different species, and details may be obtained from dealers or from the book by Margaret Ward and James Fisher. The smaller types (lovebirds and parrotlets) are fed in much the same way as budgerigars, although sunflower seed is recommended, especially at colder times of the year. For most cockatoos it has been found that a diet of wheat mixture, hemp, sunflower seed, ground-nuts, apples, and lettuce is satisfactory. Cockatiels are fed on canary seed, sunflower seed, apples, lettuce, millet, hemp, bread, and oats.

Everyone is interested in talking parrots, but it is necessary to secure a young bird, preferably a cock, and to isolate it from the others if it is to be taught successfully. It should preferably be in the charge of one person only.

# BRITISH WILD BIRDS AND THEIR IDENTIFICATION.

Wild birds attract the attention of many people—their activity by day, their plumage, and their song render them far more conspicuous than the largely nocturnal mammals—and in Great Britain alone there are several thousand bird-watchers. Merely to learn to identify birds in the hope of seeing or "spotting" rarities is, however, of little value in itself, and has been dubbed "stamp-collecting" by more serious students of ornithology, who would rather have the help of bird-watchers in other directions. Accurate recognition of different species and varieties is, of course, indispensable, but anyone really interested in birds should regard it as a means to an end and not as an end in itself. There is still much to learn concerning the habits, food, breeding, and fluctuation in numbers of many of the species in Great Britain. Indeed, there are serious gaps in our knowledge of even the commonest birds. Anyone who is prepared to take up ornithology seriously, and who is content to undertake painstaking and often somewhat mundane tasks,

"keel" (*L. carina*) to their breastbone, hence the name Carinatae.

The numbers in the illustration correspond to the following "points":—

1. Culmen, i.e., the ridge along the top of the upper "beak" or mandible.
2. Upper beak or mandible (the upper and lower beaks form the "bill").
3. Nostril.
4. Iris of the eye.
5. Crown.
6. Ear coverts.
7. Mantle.
8. Scapulars.
9. Upper tail coverts.
10. Tail-feathers or retrices.
11. Outer tail-feathers.
12. Gonyes, i.e., the ridge formed by the two parts of the under mandible.
13. Cutting edge.
14. Under-beak or mandible.
15. Lores.

THE "POINTS" OF A FLYING BIRD. (SEE TEXT)

can help materially to add to the collection of necessary facts.

In the space available it is, of course, impossible to do more than introduce the subject, but fortunately there are available many works of reference. Two in particular, are *Bird Recognition* by James Fisher (to appear eventually in four volumes at 2s. 6d. each), and *Pocket Guide to British Birds* by R. S. R. Fitter and R. A. Richardson (21s.), while for the absolute beginner *Bird Watching for Beginners* by Bruce Campbell (2s. 6d.) is excellent. The person who has taken up ornithology really seriously will find the *Handbook of British Birds* by H. F. Witherby, F. C. R. Jourdain, N. F. Ticehurst, and B. W. Tucker (in 5 volumes, each 25s.) indispensable. This is the standard work dealing in detail with all the many species of birds (over 500) that appear on "the British list." Fortunately there has recently appeared a condensed version, *The Popular Handbook of British Birds* by P. A. D. Hollom (45s.).

The accompanying illustration indicates the "points" of a typical flying bird. Actually all our birds are members of the great subdivision of *Carinatae*, or flying-bird. The other great subdivision, the *Ratitae*, or running-birds, contains such species as the ostrich, rhea, emu, and cassowary. The flying-birds all have a well-developed

16. Breast.
17. Lesser wing coverts (the row of feathers appearing just below forms the median wing-coverts).
18. Ala spuria or bastard-wing.
19. greater wing coverts.
20. Belly.
21. Tibia.
22. Tarsus.
23. Inner toe.
24. Outer toe.
25. Hind toe.
26. Secondaries.
27. Primaries.

A knowledge of these points will help the reader to understand descriptions in books of different species of birds.

The flying birds are divided into "Orders," some eighteen of which are represented on the British list. By far the largest of these Orders is (1) that containing the passerine birds (*L. passer*, a sparrow). The others are those containing: (2) swifts; (3) nightjars; (4) kingfishers, rollers, hoopoes, and bee-eaters; (5) woodpeckers and wrynecks; (6) cuckoos; (7) owls; (8) birds of prey; (9) storks, herons, bitterns, and related birds; (10) swans, geese, and ducks; (11) gannets and cormorants; (12) petrels; (13) grebes; (14) divers; (15) pigeons, doves, and sand-grouse;

(16) waders, gulls, terns, skuas, and auks; (17) bustards, cranes, and rails; and (18) game-birds.

Each of these Orders is divided into "Families," and the passerine birds are comprised of twenty such families, viz.: (i) crows and related birds; (ii) starlings; (iii) orioles; (iv) finches and buntings; (v) sparrows; (vi) larks; (vii) pipits and wagtails; (viii) creepers; (ix) nuthatches; (x) tits; (xi) shrikes; (xii) waxwings; (xiii) flycatchers; (xiv) goldcrests; (xv) warblers; (xvi) thrushes and chats; (xvii) accentors; (xviii) wrens; (xix) dippers; and (xx) swallow and martins.

These lists are formidable, but the beginner is advised to concentrate on the common species until he can identify them with ease. There are few parts of Great Britain where some bird life is not to be seen, and even London and other cities have large bird populations. Size is, of course, an important factor in recognition, and most people can learn to recognise the difference between the larger passerine birds the size of the crow (18½ in.) or jackdaw (13 in.), the intermediate ones the size of the blackbird (10 in.) or starling (8½ in.), and the smaller ones the size of the house-sparrow (5½ in.).

The following notes may help to emphasise key points in recognising some of the commoner species among three families of British passerine birds, and indicate the characters that are of help in distinguishing one bird from another.

#### CORVIDÆ (Crow family).

These are all large birds, with a length of from about 13–25 in., according to species:—

**Raven** (*Corvus corax*).—The largest British passerine (about 25 in. long), which is found mainly in mountainous and wild hilly districts and near cliffs. Has a much stouter bill than the crow, a more graduated tail, and its note in flight is a repeated "pruk, pruk" sound. It has a powerful-looking, regular wing-beat during flight, and glides and soars freely. It is capable of "aerobatics." Has a varied diet, including carrion, small animals, sometimes helpless sheep, eggs of other birds, and some vegetable matter.

**Carrion crow** (*Corvus corone*).—Uniformly black plumage. The base of the bill is fully feathered, and the bill itself is usually stouter and more curved than that of the rook. Length about 13½ in. Flight rather slow, with somewhat slower and more "deliberate" wing beats than those of rook. Usual note a hoarse croaking "kraah" or "krarr." Nests usually in forks of trees. May often be seen eating dead rabbits or other carrion on the roads.

**Hooded Crow** (*Corvus cornix*).—The "hoodie" may not really be a distinct species from the carrion-crow, for although it looks quite different, having a grey mantle, and under-parts, it interbreeds freely with the carrion-crow, and the "hybrid" young of such a mating can also breed. The hoodie is the more common species in Scotland, and predominates on most of the Scottish islands, the Isle of Man, and Ireland. Length about 18½ in.

**Rook** (*Corvus frugilegus*).—When seen on the ground the thighs appear "baggy" due to presence of loose flank feathers. Length about 18 in. The voice, usually a "caw," is distinct from the crows, while the face in the adult is described as a bare greyish white, which cause the bill to look longer and the head more peaked than those of the crow. Nests in colonies (rookeries), usually in large trees.

**Jackdaw** (*Corvus monedula*).—Often seen in company with rooks. Easily recognised by grey nape and ear-coverts. Length about 13 in. Walks with a quick, jaunty action; and altogether seems more alert than rooks or crows. Usually nests in holes, but sometimes in trees.

**Magpie** (*Pica pica*).—"Pied" plumage and a long wedge-shaped tail make recognition easy. Usually found in grassland near to thicket or other cover. Diet varied, but not uncommonly seen tackling carrion on the road. The total length is about 18 in., the tail being about 8–10 in.

**Jay** (*Garrulus glandarius*).—When seen clearly is quite unmistakable, having brownish-pink body, with whitish cream streaked with black, and wing coverts bright blue, barred with black. Length about 13 in. Is a very wary bird, and often the only view one gets of it is its white rump. It

eats many acorns, and nests mainly in woods and plantations containing oak-trees.

**Chough** (*Pyrrhocorax pyrrhocorax*).—This species is confined mainly to sea-cliffs or crags close to the coast in Cornwall, parts of Wales, the Isle of Man, one of the Scottish islands, and Western Ireland. Rather like a jackdaw in form, but without grey nape and with a characteristic long (1½–2 in.) curved red bill and red legs. Total length about 15 in.

#### STURNIDÆ (Starling family).

**Starling** (*Sturnus vulgaris*).—The starling, which originally nested in cliffs and the holes of trees—and still does in appropriate areas—has invaded man's haunts to such an extent that it now nests mainly in masonry. In London and other cities they may roost by the thousand on tall buildings, their twittering chorus being most marked. Starlings are capable, adaptable birds, whose diet may be either animal or vegetable. They have spread rapidly in the U.S.A. since they were introduced there. Although young starlings are a "mousey" brown, the adult has a characteristic "iridescent" plumage, blackish with a metallic sheen. In winter this becomes spangled. The body is plumpish and the tail short, and the beak pointed and fairly long. The walk is quick and jerky, and the bird "bustles with activity." Length about 8½ in.

#### FRINGILLIDÆ (Finch family).

This family comprises all the finch-like or seed-eating birds in Great Britain except the house-sparrow.

**Hawfinch** (*Coccothraustes coccothraustes*).—Stout "bull-necked" appearance with a relatively large bill and short tail. Length about 6½ in.

**Greenfinch** (*Chloris chloris*).—Olive-green plumage, with brighter yellow-green rump, and bright yellow patches on the primaries and at the sides of the tail. The bill is stout. Length about 5½ in.

**Goldfinch** (*Carduelis carduelis*).—Black wings, with a broad band of yellow, and black tail. Red, white, and black pattern on head. Quills of wings and tail have white terminal spot. Length about 4½ in.

**Siskin** (*Carduelis spinus*).—The male has predominantly yellow-green plumage, with black crown and chin and a yellow rump. The female is duller and greyer, without any black on the head. Length about 4½ in.

**Lesser Redpoll** (*Carduelis flammea cabaret*).—In breeding season its favourite haunts include birch copses. Crimson forehead and black chin. The note during flight is distinctive, and is described as a twittering "chuch-uch-uch-uch." Length about 4½ in.

**British Bullfinch** (*Pyrrhula pyrrhula nesae*).—This bird is quite unmistakable at close quarters. Stout bill, grey back, black cap, wings and tail, and rose-red underparts in male, pinkish-grey underparts in female. The bird is secretive in habits, however, and often only the pure-white rump is seen. Length about 5½ in. The call-note is a long piping "deu" sound.

**British Chaffinch** (*Fringilla coelebs gentleri*).—This bird is widely distributed over almost the whole of Great Britain, and frequents gardens, hedgerows, and woods. During flight a broad white shoulder patch is evident, especially in the male, while the white on the outer tail feathers is conspicuous also. The rump is yellowish green. On the ground the species is quite distinctive, the male having a beautiful slate-blue crown and nape, chestnut mantle, pinkish-brown sides of head and underparts, and blackish wings and tail with the white marks that show up so well during flight. The female is a rather pale yellowish brown, lighter below. Length about 6 in.

**Brambling** (*Fringilla montifringilla*).—The shape of this bird is similar to that of the chaffinch, but the white rump is conspicuous during flight. On the ground the breast of both sexes is seen to be orange-buff, while there is a shoulder patch of similar colour on the male. Head brown or blackish. In England and Wales is a winter-visitor or migrant. Length about 5½ in.

This family comprises also the many species of buntings that occur, and for the individual recognition of which the reader is advised to study coloured plates or original specimens in a museum.

# Ready Reckoner

# Ready Reckoner

## From One-sixteenth of a Penny to Twenty-one Shillings

In the following tables any number of articles, separate weights or measures, days, weeks, months or years—from 1 to 5,000—are reckoned, at amounts from a sixteenth of one penny to one guinea. Up to 20 each number is worked through progressively in the shorter tables on this page; then follows 25—as a quarter of a hundred—and every multiple of ten next in order, with 52—as the number standing for the weeks in a year—interpolated in its proper place.

In the longer tables—from the next page to the end—every number from 1 to 100 is reckoned out. Beyond the number 100, the figures standing for multiples of dozens up to the gross (144) have a line each, as has also 112, the number of pounds in a cwt.; with an entry for 365, the number of days in the year, breaking the even hundred progression; and one at 2,240—for the purpose of showing at a glance what the cost per ton comes to of anything priced at the amount per pound shown by the table—inserted between the 2,000 and 3,000.

The reckoning for every possible combination of whole numbers can thus be readily arrived at, where not expressly given, by adding together the items indicating the values attached to composing numbers. Thus 3,366 articles at one-twelfth of a penny each would come to the total of 3,000 + 300 + 60 + 6, or, as will be seen, £1 0s. 10d. + 2s. 1d. + 5d. + 0½d., an aggregate equalling £1 3s. 4½d.

# DECORATIONS FOR VALOUR AND GALLANTRY

**THE VICTORIA CROSS (V.C.)**  
Symbol of the highest acts of bravery in the face of the enemy. Instituted in 1856.

**THE GEORGE CROSS (G.C.)**  
Awarded to men and women for acts of great heroism in circumstances of extreme danger. Instituted in 1940.

**THE DISTINGUISHED SERVICE ORDER (D.S.O.)**  
Awarded only to an officer in any of the three Services as a reward for distinguished service in war. Instituted in 1886.

**THE DISTINGUISHED SERVICE CROSS (D.S.C.)**  
Awarded to naval and marine officers of the relative rank of commander and below for distinguished service in the face of the enemy.

**THE MILITARY CROSS (M.C.)**  
Awarded for distinguished service in war by officers of the rank of Captain and below. Instituted in 1914.

**THE DISTINGUISHED FLYING CROSS (D.F.C.)**  
Awarded for acts of valour and devotion to duty to officers and warrant officers of the R.A.F. whilst flying on active operations against the enemy. Instituted in 1919.

**THE AIR FORCE CROSS (A.F.C.)**  
Awarded to officers and warrant officers of the R.A.F. for acts of valour and devotion to duty whilst flying though not on active operations against the enemy. Instituted in 1919.

**THE ALBERT MEDAL (A.M.)**  
Awarded for heroic acts in saving, or endeavouring to save, life at sea. Instituted in 1866. Two classes: 1st class Gold, 2nd class Bronze.

**THE ALBERT MEDAL (A.M.)**  
Awarded for heroic acts in saving, or endeavouring to save, life on land. Instituted in 1877. Two classes: 1st class Gold, 2nd class Bronze.

**THE DISTINGUISHED CONDUCT MEDAL (D.C.M.)**  
Awarded to N.C.O.s and men of the army for distinguished conduct in the field. Instituted in 1854.

**THE CONSPICUOUS GALLANTRY MEDAL (C.G.M.)**  
Awarded to petty officers and men of the R.N. and N.C.O.s and men of the R.M. for acts of conspicuous gallantry in the face of the enemy. Originated for the Crimean war only, and reinstituted in 1874.

**THE GEORGE MEDAL (G.M.)**  
Awarded, for acts of great heroism, to men and women. Instituted in 1940.

**THE DISTINGUISHED SERVICE MEDAL (D.S.M.)**  
Awarded to petty officers and men of the R.N. and N.C.O.s and men of the R.M. for courageous service in war. Instituted in 1914.

**THE MILITARY MEDAL (M.M.)**  
Awarded to N.C.O.s and men of the army for individual acts of bravery. It may be awarded to women for devotion to duty under fire. Instituted in 1916.

**THE DISTINGUISHED FLYING MEDAL (D.F.M.)**  
Awarded to N.C.O.s and men of the R.A.F. for acts of valour or devotion to duty whilst flying in active operations against the enemy. Instituted in 1919.

**THE AIR FORCE MEDAL (A.F.M.)**  
Awarded to N.C.O.s and men of the R.A.F. for acts of valour or devotion to duty when flying, not on active operations against the enemy. Instituted in 1919.

in Despatches

In showing precedence of Orders, only the highest Class is considered.

The Class of an Order affects the precedence considerably, for example, the 1st, 2nd and 3rd Class of the Order of the British Empire come before the D.S.O., whereas the 4th Class (O.B.E.) and the 5th Class (M.B.E.) follow the D.S.O.
